## Statement

**Copyright ©2025 Xiaohua Semiconductor Co., Ltd. All Rights Reserved.**

All intellectual property rights related to the information contained in this document and its annexes belongs to Xiaohua Semiconductor Co., Ltd. (hereinafter referred to as "XHSC"). The customer only has the right to use the information contained in this document and its annexes. Without the written permission of XHSC, it is forbidden to extract, copy, modify, use or spread any part or all of this document in any form.

### Trademark Statement

**XHSC** XIAOHUA SEMICONDUCTOR, **XHSC**, and other trademarks are the trademarks of XHSC. All other products or services shown on XHSC products are the property of their respective owners.

### Precautions

- XHSC reserves the right to change, correct, enhance and modify the product and/or this document at any time without notice. Users can get the latest information before placing orders. XHSC products are sold in accordance with the sales terms and conditions stated in the basic purchase and sale contract.
- It is the customer's responsibility to select the appropriate XHSC product for your application and to design, validate and test your application to ensure that your application meets the appropriate standards and any safety, security or other requirements. The customer shall be solely responsible for this.
- XHSC hereby acknowledges that no intellectual property license has been granted by express or implied means.
- The resale of XHSC Products shall be invalidated by any warranty commitment of XHSC to such Products if its terms are different from those set forth herein.
- Information in this notification replaces information in previous versions.

## Preface

### Bit/Bit Field

A register contains a bit (one bit wide) or a bit field (multiple bit width), and the bit field is usually described as [y:x], starting from the x bit and ending at the y bit. Unless otherwise specified, decimal numbers are used in the bit field.

It is not recommended to use unspecified fields; otherwise, unpredictable consequences may be caused.

### Register Address

The address of each register can be obtained by the base address of the system address division and the offset address of the register (see the "Register List" of each module for details).

### Access Type

The following abbreviations are used for register description:

| Access Type | Description                                                                     |
|-------------|---------------------------------------------------------------------------------|
| RW          | Readable and writable.                                                          |
| RO          | Read only. Writes are ignored.                                                  |
| WO          | Write only. Read value undefined.                                               |
| RWA         | Readable and writable. Writable only when unlocked or in safe mode.             |
| RWC         | Readable and writable. Writing any value clears this bit.                       |
| RC          | Read only. Writes are ignored. This bit is cleared automatically after reading. |
| RS          | Read only. Writes are ignored. This bit is set automatically after reading.     |

### Number Format

- 0x prefix is used for hexadecimal numbers
- 0b prefix is used for binary numbers
- Numbers without prefix are in decimal representation

### Reserved (Res.)

Registers and bit fields marked with *Reserved* are reserved for future use. These should be written to their reset value unless otherwise stated in the Register Description. The read value of Reserved bit may be different in different devices or features.

### Reset Value (Reset)

The reset value indicates the value after the register is reset. Registers need to be initialized and reset before use; otherwise, unpredictable consequences may be caused.

### Peripheral Availability Description

For HC32A4A8 Series 32-bit ARM® Cortex®-M4 Microcontroller supported peripherals and their numbers, refer to the corresponding "Datasheet".

### Security Statement

There may be potential security problems due to the use of a certain function or protocol, which need to be declared to remind users and avoid security risks.

| 5.4 Register Description.....                                                      | 104        |
| 5.4.1 Register List.....                                                           | 104        |
| 5.4.2 CMU XTAL Config Register (CMU_XTALCFGR).....                                 | 106        |
| 5.4.3 CMU XTAL Stable Control Register (CMU_XTALSTBCR).....                        | 107        |
| 5.4.4 CMU XTAL Fractional Frequency Division Config Register (CMU_XTALDIVR).....   | 108        |
| 5.4.5 CMU XTAL Fractional Frequency Division Control Register (CMU_XTALDIVCR)..... | 108        |
| 5.4.6 CMU XTAL Control Register (CMU_XTALCR).....                                  | 109        |
| 5.4.7 CMU XTAL Clock Stop Detect Control Register (CMU_XTALSTDCR).....             | 110        |
| 5.4.8 CMU XTAL Clock Stop Detect Status Register (CMU_XTALSTDSR).....              | 111        |
| 5.4.9 CMU XTAL32 Config Register (CMU_XTAL32CFGR).....                             | 112        |
| 5.4.10 CMU XTAL32 Filter Control Register (CMU_XTAL32NFR).....                     | 113        |
| 5.4.11 CMU XTAL32 Control Register (CMU_XTAL32CR).....                             | 113        |
| 5.4.12 CMU HRC Trimming Register (CMU_HRCTRM).....                                 | 114        |
| 5.4.13 CMU HRC Control Register (CMU_HRCCR).....                                   | 115        |
| 5.4.14 CMU MRC Trimming Register (CMU_MRCTRM).....                                 | 116        |
| 5.4.15 CMU MRC Control Register (CMU_MRCCR).....                                   | 117        |
| 5.4.16 CMU LRC Trimming Register (CMU_LRCTRM).....                                 | 118        |
| 5.4.17 CMU LRC Control Register (CMU_LRCCR).....                                   | 119        |
| 5.4.18 CMU RTCLRC Trimming Register (CMU_RTCLRCTRM).....                           | 120        |
| 5.4.19 CMU PLLH Config Register (CMU_PLLHCFGR).....                                | 121        |
| 5.4.20 CMU PLLH Control Register (CMU_PLLHCR).....                                 | 123        |
| 5.4.21 CMU PLLA Config Register (CMU_PLLACFGR).....                                | 124        |
| 5.4.22 CMU PLLA Control Register (CMU_PLLACR).....                                 | 126        |
| 5.4.23 CMU Clock Source Stable Status Register (CMU_OSCSTBSR).....                 | 127        |
| 5.4.24 CMU System Clock Source Switch Register (CMU_CKSWR).....                    | 128        |
| 5.4.25 CMU Clock Divider Config Register (CMU_SCFGR).....                          | 129        |
| 5.4.26 CMU USB Clock Config Register (CMU_USBCKCFGR).....                          | 132        |
| 5.4.27 CMU CAN Clock Config Register (CMU_CANCKCFGR).....                          | 133        |
| 5.4.28 CMU ADC/DAC Clock Config Register (CMU_PERICKSEL).....                      | 136        |
| 5.4.29 CMU Debug Clock Config Register (CMU_TPIUCKCFGR).....                       | 137        |
| 5.4.30 CMU I2S Clock Config Register (CMU_I2SCKCFGR).....                          | 138        |
| 5.4.31 CMU MCO1 Clock Output Config Register (CMU_MCO1CFGR).....                   | 140        |
| 5.4.32 CMU MCO2 Clock Output Config Register (CMU_MCO2CFGR).....                   | 141        |
| 5.4.33 FCM Lower Limit Control Register (FCMn_LVR) (n=1-4).....                    | 142        |
| 5.4.34 FCM Upper Limit Control Register (FCMn_UVR) (n=1-4).....                    | 142        |
| 5.4.35 FCM Counter Register (FCMn_CNTR) (n=1-4).....                               | 143        |
| 5.4.36 FCM Start Control Register (FCM_STR).....                                   | 143        |
| 5.4.37 FCM Measurement Control Register (FCMn_MCCR) (n=1-4).....                   | 144        |
| 5.4.38 FCM Reference Control Register (FCMn_RCCR) (n=1-4).....                     | 145        |
| 5.4.39 FCM Reset Interrupt Control Register (FCMn_RIER) (n=1-4).....               | 147        |
| 5.4.40 FCM Flag Register (FCM_SR).....                                             | 148        |
| 5.4.41 FCM Flag Clear Register (FCMn_CLR) (n=1-4).....                             | 150        |
| <b>6 Power Control (PWC).....</b>                                                  | <b>151</b> |
| 6.1 Introduction.....                                                              | 151        |

|                                                                          |     |

| 21.3.18 Interrupt and Events.....                                          | 627 |
| 21.4 Operation Example.....                                                | 629 |
| 21.4.1 Basic Counting and Interrupt Action.....                            | 629 |
| 21.4.2 Compare Output and Interrupt Action.....                            | 629 |
| 21.4.3 Capture Input and Interrupt Action.....                             | 629 |
| 21.4.4 Buffer Transmission Action (Period Reference Value).....            | 630 |
| 21.4.5 Buffer Transmission Action (General Compare Reference Value).....   | 630 |
| 21.4.6 Buffer Transmission Action (Special Compare Reference Value).....   | 630 |
| 21.4.7 Buffer Transmission Action (Dead Zone Reference Value).....         | 631 |
| 21.4.8 Synchronization Start Action (Software Mode).....                   | 631 |
| 21.4.9 Synchronization Start Action (Hardware Mode).....                   | 631 |
| 21.4.10 Quadrature Encoding Count Action (2-phase).....                    | 632 |
| 21.4.11 Quadrature Encoding Count Action (3-phase).....                    | 632 |
| 21.4.12 Single Channel PWM Output.....                                     | 633 |
| 21.4.13 Complementary PWM Output (Software Dead Zone).....                 | 633 |
| 21.4.14 Complementary PWM Output (Hardware Dead Zone).....                 | 633 |
| 21.4.15 EMB Monitoring and Interrupt Action.....                           | 633 |
| 21.5 Register Description.....                                             | 635 |
| 21.5.1 Register List.....                                                  | 635 |
| 21.5.2 General Count Value Register (TMR6_CNTER).....                      | 639 |
| 21.5.3 General Refresh Value Register (TMR6_UPDAR).....                    | 639 |
| 21.5.4 General Period Reference Value Register (TMR6_PERmR) (m=A-C).....   | 640 |
| 21.5.5 General Compare Reference Value Register (TMR6_GCMmR) (m=A-F).....  | 640 |
| 21.5.6 Special Compare Reference Value Register (TMR6_SCMmR) (m=A-F).....  | 641 |
| 21.5.7 Dead Time Reference Value Register (TMR6_DTmnR) (m=U/D, n=A/B)..... | 641 |
| 21.5.8 General Control Register (TMR6_GCONR).....                          | 642 |
| 21.5.9 Interrupt Control Register (TMR6_ICONR).....                        | 644 |
| 21.5.10 Buffer Control Register (TMR6_BCONR).....                          | 646 |
| 21.5.11 Dead Zone Control Register (TMR6_DCONR).....                       | 650 |
| 21.5.12 Port Control Register A (TMR6_PCNAR).....                          | 651 |
| 21.5.13 Port Control Register B (TMR6_PCNBR).....                          | 655 |
| 21.5.14 Filter Control Register (TMR6_FCNGR).....                          | 659 |
| 21.5.15 Valid Period Register (TMR6_VPERR).....                            | 660 |
| 21.5.16 Status Flag Register (TMR6_STFLR).....                             | 661 |
| 21.5.17 Hardware Start Event Selection Register (TMR6_HSTAR).....          | 663 |
| 21.5.18 Hardware Stop Event Selection Register (TMR6_HSTPR).....           | 666 |
| 21.5.19 Hardware Clear Event Selection Register (TMR6_HCLRR).....          | 669 |

|                                                                                    |            |
|------------------------------------------------------------------------------------|------------|
| 21.5.20 Hardware Refresh Event Selection Register (TMR6_HUPDR).....                | 672        |
| 21.5.21 Hardware Capture Event Selection Register A (TMR6_HCPAR).....              | 675        |
| 21.5.22 Hardware Capture Event Selection Register B (TMR6_HCPBR).....              | 678        |
| 21.5.23 Hardware Count Up Event Select Register (TMR6_HCUPR).....                  | 681        |
| 21.5.24 Hardware Count Down Event Select Register (TMR6_HCDOR).....                | 685        |
| 21.5.25 PTO Pulse Number Register (TMR6_PTNUMR).....                               | 689        |
| 21.5.26 PTO Pulse Period Register (TMR6_PTPERR).....                               | 689        |
| 21.5.27 PTO Algorithm Period Remainder Register (TMR6_PTRMDR).....                 | 690        |
| 21.5.28 PTO Mode Control Register (TMR6_PTCTLR).....                               | 691        |
| 21.5.29 PTO A-phase Output Position Register (TMR6_PTAOPR).....                    | 691        |
| 21.5.30 PTO B-phase Output Position Register (TMR6_PTBOPR).....                    | 692        |
| 21.5.31 PTO Z-phase Output Start Position Register (TMR6_PTZOSPR).....             | 692        |
| 21.5.32 PTO Z-phase Output End Position Register (TMR6_PTZOEPR).....               | 692        |
| 21.5.33 PTO Z-phase Output Pulse Width Compression B Register (TMR6_PTZCMPBR)..... | 693        |
| 21.5.34 PTO Full Circle Pulse Count Register (TMR6_PTZPERR).....                   | 693        |
| 21.5.35 PTO Pulse Initial Position Register (TMR6_PTPSPR).....                     | 694        |

| 36.2 Features.....                                               | 1348        |
| 36.3 Functional Description.....                                 | 1349        |
| 36.3.1 System Block Diagram.....                                 | 1349        |
| 36.3.2 Pin Description.....                                      | 1349        |
| 36.3.3 Operating Mode.....                                       | 1349        |
| 36.3.4 Baud Rate Setting.....                                    | 1351        |
| 36.3.5 Transmission Processing.....                              | 1353        |
| 36.3.6 Reception Processing.....                                 | 1355        |
| 36.3.7 Error Handling.....                                       | 1356        |
| 36.3.8 BUS OFF.....                                              | 1356        |
| 36.3.9 Arbitration lost Position Capture.....                    | 1357        |
| 36.3.10 Time-Triggered TTCAN.....                                | 1357        |
| 36.3.11 TDC and RDC.....                                         | 1359        |
| 36.3.12 Upward Compatibility with CAN-FD Function.....           | 1359        |
| 36.3.13 RAM ECC Function.....                                    | 1360        |
| 36.3.14 Software Reset Function.....                             | 1360        |
| 36.3.15 Interrupt.....                                           | 1362        |
| 36.4 Register Description.....                                   | 1363        |
| 36.4.1 Register List.....                                        | 1363        |
| 36.4.2 CAN Receive BUF Register (CAN_RBUF).....                  | 1365        |
| 36.4.3 CAN Transmit BUF Register (CAN_TBUF).....                 | 1368        |
| 36.4.4 CAN Configuration and Status Register (CAN_CFG_STAT)..... | 1370        |
| 36.4.5 CAN Command Register (CAN_TCMD).....                      | 1372        |
| 36.4.6 CAN Transmit Control Register (CAN_TCTRL).....            | 1374        |
| 36.4.7 CAN Receive Control Register (CAN_RCTRL).....             | 1376        |

|                                                                             |             |
|-----------------------------------------------------------------------------|-------------|
| 36.4.8 CAN Receive and Transmit Interrupt Enable Register (CAN_RTIE).....   | 1377        |
| 36.4.9 CAN Receive and Transmit Interrupt Flag Register (CAN_RTIF).....     | 1378        |
| 36.4.10 CAN Error Interrupt Enable and Flag Register (CAN_ERRINT).....      | 1380        |
| 36.4.11 CAN Slow Bit Timing Register (CAN_SBT).....                         | 1381        |
| 36.4.12 CAN Fast Bit Timing Register (CAN_FBT).....                         | 1382        |
| 36.4.13 CAN Transmitter Delay Compensation Register (CAN_TDC).....          | 1383        |
| 36.4.14 CAN Error and Arbitration Lost Capture Register (CAN_EALCAP).....   | 1384        |
| 36.4.15 CAN Warning Limits Register (CAN_LIMIT).....                        | 1385        |
| 36.4.16 CAN Receive Error Counter Register (CAN_RECNT).....                 | 1385        |
| 36.4.17 CAN Transmit Error Counter Register (CAN_TECNT).....                | 1386        |
| 36.4.18 CAN Filter Group Control Register (CAN_ACFCTRL).....                | 1387        |
| 36.4.19 CAN Filter Group Enable Register (CAN_ACFEN).....                   | 1388        |
| 36.4.20 CAN Filter Group Code and Mask Register (CAN_ACF).....              | 1390        |
| 36.4.21 TTCAN TB Slot Pointer Register (CAN_TB SLOT).....                   | 1391        |
| 36.4.22 TTCAN Time Trigger Configuration Register (CAN_TTCFG).....          | 1392        |
| 36.4.23 TTCAN Reference Message Register (CAN_REF_MSG).....                 | 1394        |
| 36.4.24 TTCAN Trigger Configuration Register (CAN_TRG_CFG).....             | 1395        |
| 36.4.25 TTCAN Trigger Time Register (CAN_TT_TRIG).....                      | 1396        |
| 36.4.26 TTCAN Trigger Watchdog Time Register (CAN_TT_WTRIG).....            | 1396        |
| 36.4.27 CAN RAM Check Control Register (CAN_RAM_CKCR).....                  | 1397        |
| 36.4.28 CAN RAM Check Status Register (CAN_RAM_CKSR).....                   | 1398        |
| 36.4.29 CAN RAM Error Injection Enable Register (CAN_RAM_EIEN).....         | 1398        |
| 36.4.30 CAN RAM Error Injection Bit Enable Register 0 (CAN_RAM_EIBIT0)..... | 1399        |
| 36.4.31 CAN RAM Error Injection Bit Enable Register 1 (CAN_RAM_EIBIT1)..... | 1399        |
| 36.4.32 CAN RAM ECC Error Address Register (CAN_RAM_ECCERRADDR).....        | 1400        |
| 36.4.33 CAN System Control Register (CAN_SYCTLREG).....                     | 1400        |
| 36.5 Precautions.....                                                       | 1401        |
| 36.5.1 CAN Bus Anti-Interference Measures.....                              | 1401        |
| 36.5.2 CAN Controller Noise Constraints.....                                | 1401        |
| <b>37 Controller Area Network (MCAN).....</b>                               | <b>1402</b> |
| 37.1 Introduction.....                                                      | 1402        |
| 37.2 Features.....                                                          | 1402        |
| 37.3 Functional Description.....                                            | 1403        |
| 37.3.1 MCAN System Block Diagram.....                                       | 1403        |
| 37.3.2 Pin Description.....                                                 | 1404        |
| 37.3.3 Working Mode.....                                                    | 1404        |
| 37.3.4 Timestamp Generation.....                                            | 1412        |
| 37.3.5 Timeout Counter.....                                                 | 1413        |
| 37.3.6 Reception Processing.....                                            | 1413        |
| 37.3.7 Transmission Processing.....                                         | 1420        |
| 37.3.8 FIFO Confirmation Processing.....                                    | 1424        |
| 37.3.9 Message RAM.....                                                     | 1425        |
| 37.4 Register Description.....                                              | 1437        |
| 37.4.1 Register List.....                                                   | 1437        |
| 37.4.2 MCAN Byte Order Register (MCAN_ENDN).....                            | 1440        |

|                                                                                             |      |
|---------------------------------------------------------------------------------------------|------|
| 37.4.3 MCAN Data Bit Time and Prescaler Register (MCAN_DBTP).....                           | 1441 |
| 37.4.4 MCAN Test Register (MCAN_TEST).....                                                  | 1443 |
| 37.4.5 MCAN RAM Watchdog Register (MCAN_RWD).....                                           | 1445 |
| 37.4.6 MCAN CC Control Register (MCAN_CCCR).....                                            | 1446 |
| 37.4.7 MCAN Nominal Bit Time and Prescaler Register (MCAN_NBTP).....                        | 1449 |
| 37.4.8 MCAN Timestamp Counter Configuration Register (MCAN_TSCC).....                       | 1450 |
| 37.4.9 MCAN Timestamp Counter Value Register (MCAN_TSCV).....                               | 1451 |
| 37.4.10 MCAN Timeout Counter Configuration Register (MCAN_TOCC).....                        | 1452 |
| 37.4.11 MCAN Timeout Counter Value Register (MCAN_TOCV).....                                | 1453 |
| 37.4.12 MCAN Error Counter Register (MCAN_ECR).....                                         | 1454 |
| 37.4.13 MCAN Protocol Status Register (MCAN_PSR).....                                       | 1455 |
| 37.4.14 MCAN Transmit Delay Compensation Register (MCAN_TDCR).....                          | 1459 |
| 37.4.15 MCAN Interrupt Register (MCAN_IR).....                                              | 1460 |
| 37.4.16 MCAN Interrupt Enable Register (MCAN_IE).....                                       | 1464 |
| 37.4.17 MCAN Interrupt Line Selection Register (MCAN_ILS).....                              | 1467 |
| 37.4.18 MCAN Interrupt Line Enable Register (MCAN_ILE).....                                 | 1470 |
| 37.4.19 MCAN Global Filter Configuration Register (MCAN_GFC).....                           | 1471 |
| 37.4.20 MCAN Standard ID Filter Configuration Register (MCAN_SIDFC).....                    | 1472 |
| 37.4.21 MCAN Extended ID Filter Configuration Register (MCAN_XIDFC).....                    | 1473 |
| 37.4.22 MCAN Extended ID and Mask Register (MCAN_XIDAM).....                                | 1474 |
| 37.4.23 MCAN High Priority Message Status Register (MCAN_HPMS).....                         | 1475 |
| 37.4.24 MCAN New Data 1 Register (MCAN_NDAT1).....                                          | 1476 |
| 37.4.25 MCAN New Data 2 Register (MCAN_NDAT2).....                                          | 1477 |
| 37.4.26 MCAN Receive FIFO0 Configuration Register (MCAN_RXF0C).....                         | 1478 |
| 37.4.27 MCAN Receive FIFO0 Status Register (MCAN_RXF0S).....                                | 1479 |
| 37.4.28 MCAN Receive FIFO0 Acknowledge Register (MCAN_RXF0A).....                           | 1480 |
| 37.4.29 MCAN Receive Buffer Configuration Register (MCAN_RXBC).....                         | 1480 |
| 37.4.30 MCAN Receive FIFO1 Configuration Register (MCAN_RXF1C).....                         | 1481 |
| 37.4.31 MCAN Receive FIFO1 Status Register (MCAN_RXF1S).....                                | 1482 |
| 37.4.32 MCAN Receive FIFO1 Acknowledge Register (MCAN_RXF1A).....                           | 1483 |
| 37.4.33 MCAN Receive Buffer and FIFO Element Size Configuration Registers (MCAN_RXESC)..... | 1484 |
| 37.4.34 MCAN Transmit Buffer Configuration Register (MCAN_TXBC).....                        | 1485 |
| 37.4.35 MCAN Transmit FIFO/Queue Status Register (MCAN_TXFQS).....                          | 1486 |
| 37.4.36 MCAN Transmit Buffer Element Size Configuration Register (MCAN_TXESC).....          | 1487 |
| 37.4.37 MCAN Transmit Buffer Request Pending Register (MCAN_TXBRP).....                     | 1488 |
| 37.4.38 MCAN Transmit Buffer Add Request Register (MCAN_TXBAR).....                         | 1489 |
| 37.4.39 MCAN Transmit Buffer Cancel Request Register (MCAN_TXBCR).....                      | 1490 |
| 37.4.40 MCAN Transmit Buffer Transmit Occurred Register (MCAN_TXBTO).....                   | 1491 |
| 37.4.41 MCAN Transmit Buffer Cancel Completed Register (MCAN_TXBCF).....                    | 1492 |
| 37.4.42 MCAN Transmit Buffer Transmit Interrupt Enable Register (MCAN_TXBTIE).....          | 1493 |
| 37.4.43 MCAN Transmit Buffer Cancel Completed Interrupt Enable Register (MCAN_TXBCIE).....  | 1493 |
| 37.4.44 MCAN Transmit Event FIFO Configuration Register (MCAN_TXEFC).....                   | 1494 |
| 37.4.45 MCAN Transmit Event FIFO Status Register (MCAN_TXEFS).....                          | 1495 |
| 37.4.46 MCAN Transmit Event FIFO Acknowledge Register (MCAN_TXEFA).....                     | 1496 |
| 37.4.47 MCAN Message RAM Check Control Register (MCANRAM_CKCR).....                         | 1497 |

|                                                                                      |             |

| 42.4.4 PKE Register.....                                                 | 1821        |
| 42.4.5 SKE Register.....                                                 | 1839        |
| <b>43 CRC Operation (CRC).....</b>                                       | <b>1850</b> |
| 43.1 Introduction.....                                                   | 1850        |
| 43.2 Functional Description.....                                         | 1850        |
| 43.2.1 Function Block Diagram.....                                       | 1850        |
| 43.2.2 CRC Parameter Model.....                                          | 1850        |
| 43.2.3 CRC16 Encoding Mode.....                                          | 1851        |
| 43.2.4 CRC16 Check Mode.....                                             | 1851        |
| 43.2.5 CRC32 Encoding Mode.....                                          | 1852        |
| 43.2.6 CRC32 Check Mode.....                                             | 1852        |
| 43.2.7 CRC64 Encoding Mode.....                                          | 1852        |
| 43.2.8 CRC64 Check Mode.....                                             | 1853        |
| 43.3 Register Description.....                                           | 1854        |
| 43.3.1 Register List.....                                                | 1854        |
| 43.3.2 Control Register (CRC_CR).....                                    | 1855        |
| 43.3.3 Result Register 1 (CRC_RESULT1).....                              | 1856        |
| 43.3.4 Result Register 2 (CRC_RESULT2).....                              | 1856        |
| 43.3.5 Data Register (CRC_DAT).....                                      | 1857        |
| <b>44 Data Computing Unit (DCU).....</b>                                 | <b>1858</b> |
| 44.1 Introduction.....                                                   | 1858        |
| 44.2 Features.....                                                       | 1858        |
| 44.3 Functional Description.....                                         | 1858        |
| 44.3.1 Addition Mode.....                                                | 1858        |
| 44.3.2 Subtraction Mode.....                                             | 1859        |
| 44.3.3 Hardware Trigger Start Mode.....                                  | 1859        |
| 44.3.4 Comparative Mode.....                                             | 1860        |
| 44.3.5 Triangle Wave Output Mode.....                                    | 1860        |
| 44.3.6 Increment Sawtooth Wave Output Mode.....                          | 1862        |
| 44.3.7 Decrement Sawtooth Wave Output Mode.....                          | 1863        |
| 44.3.8 Interrupt and Event.....                                          | 1864        |
| 44.4 Register Description.....                                           | 1865        |
| 44.4.1 Register List.....                                                | 1865        |
| 44.4.2 DCU Control Register (DCU_CTL).....                               | 1866        |
| 44.4.3 DCU Flag Register (DCU_FLAG) (DCU1-DCU4).....                     | 1868        |
| 44.4.4 DCU Flag Register (DCU_FLAG) (DCU5-DCU8).....                     | 1870        |
| 44.4.5 DCU Data Register (DCU_DATAx) (x=0-2).....                        | 1871        |
| 44.4.6 DCU Flag Reset Register (DCU_FLAGCLR) (DCU1-DCU4).....            | 1875        |
| 44.4.7 DCU Flag Reset Register (DCU_FLAGCLR) (DCU5-DCU8).....            | 1876        |
| 44.4.8 DCU Interrupt and Event Register (DCU_INTEVTSEL) (DCU1-DCU4)..... | 1877        |
| 44.4.9 DCU Interrupt and Event Register (DCU_INTEVTSEL) (DCU5-DCU8)..... | 1880        |
| <b>45 Math Arithmetical Unit (MAU).....</b>                              | <b>1883</b> |
| 45.1 Introduction.....                                                   | 1883        |
| 45.2 Functional Description.....                                         | 1883        |
| 45.2.1 Square Root Operation.....                                        | 1883        |

|                                                                 |             |
|-----------------------------------------------------------------|-------------|
| 45.2.2 Sine Operation.....                                      | 1884        |
| 45.2.3 Interrupt and Event Output.....                          | 1884        |
| 45.3 Register Description.....                                  | 1885        |
| 45.3.1 Register List.....                                       | 1885        |
| 45.3.2 Control State Register (MAU_CSR).....                    | 1886        |
| 45.3.3 Data Input Register 0 (MAU_DTR0).....                    | 1887        |
| 45.3.4 Result Output Register 0 (MAU_RTR0).....                 | 1888        |
| 45.3.5 Data Input Register 1 (MAU_DTR1).....                    | 1888        |
| 45.3.6 Result Output Register 1 (MAU_RTR1).....                 | 1889        |
| <b>46 Filter Math Accelerator (FMAC).....</b>                   | <b>1890</b> |
| 46.1 Introduction.....                                          | 1890        |
| 46.2 Features.....                                              | 1890        |

| 46.3.1 Basic Block Diagram.....                                 | 1890        |
| 46.3.2 Operating Procedures.....                                | 1891        |
| 46.3.3 Module Enable.....                                       | 1891        |
| 46.3.4 Coefficient Normalization.....                           | 1891        |
| 46.3.5 Interrupt and Events.....                                | 1891        |
| 46.4 Register Description.....                                  | 1892        |
| 46.4.1 Register List.....                                       | 1892        |
| 46.4.2 Module Enable Register (FMAC_ENR).....                   | 1893        |
| 46.4.3 Basic Control Register (FMAC_CTR).....                   | 1894        |
| 46.4.4 Interrupt Control Register (FMAC_IER).....               | 1895        |
| 46.4.5 Data Input Register (FMAC_DTR).....                      | 1895        |
| 46.4.6 Filter Coefficient Register n (FMAC_CORn) (n=0-16).....  | 1896        |
| 46.4.7 Result Output Register 0 (FMAC_RTR0).....                | 1896        |
| 46.4.8 Result Output Register 1 (FMAC_RTR1).....                | 1897        |
| 46.4.9 Operation Status Register (FMAC_STR).....                | 1897        |
| <b>47 Error Management Unit (ERMU).....</b>                     | <b>1898</b> |
| 47.1 Introduction.....                                          | 1898        |
| 47.2 Features.....                                              | 1898        |
| 47.3 Functional Description.....                                | 1899        |
| 47.3.1 Function Block Diagram.....                              | 1899        |
| 47.3.2 Error Output Channel.....                                | 1900        |
| 47.3.3 Wait Timer.....                                          | 1902        |
| 47.3.4 Reset Request.....                                       | 1902        |
| 47.3.5 Interrupt Request.....                                   | 1902        |
| 47.3.6 Pseudo Error Trigger.....                                | 1903        |
| 47.3.7 Interrupt.....                                           | 1903        |
| 47.3.8 Error Source.....                                        | 1903        |
| 47.4 Operation Example.....                                     | 1906        |
| 47.4.1 ERMU Error Management Example.....                       | 1906        |
| 47.5 Register Description.....                                  | 1907        |
| 47.5.1 Register List.....                                       | 1907        |
| 47.5.2 Error Output y Control Register (ERMU_EOyC) (y=0-3)..... | 1908        |

|                                                                                 |             |
|---------------------------------------------------------------------------------|-------------|
| 47.5.3 Error Output y Status Register (ERMU_EOyS) (y=0-3).....                  | 1909        |
| 47.5.4 Error Output y Clear Timer Count Register (ERMU_EOyCTCNT) (y=0-3).....   | 1909        |
| 47.5.5 Error Output y Clear Timer Compare Register (ERMU_EOyCTCMP) (y=0-3)..... | 1910        |
| 47.5.6 Error Output y Flip Timer Control Register (ERMU_EOyTTC) (y=0-3).....    | 1910        |
| 47.5.7 Error Output y Flip Timer Compare Register (ERMU_EOyTTCMP) (y=0-3).....  | 1911        |
| 47.5.8 Error Output y Mask 0 Register (ERMU_EOyOM0) (y=0-3).....                | 1911        |
| 47.5.9 Error Output y Mask 1 Register (ERMU_EOyOM1) (y=0-3).....                | 1912        |
| 47.5.10 Wait Timer z Control Register (ERMU_WTzC) (z= 0-3).....                 | 1912        |
| 47.5.11 Wait Timer z Status Register (ERMU_WTzS) (z= 0-3).....                  | 1913        |
| 47.5.12 Wait Timer z Count Register (ERMU_WTzCNT) (z= 0-3).....                 | 1913        |
| 47.5.13 Wait Timer z Compare Register (ERMU_WTzCMP) (z=0-3).....                | 1914        |
| 47.5.14 Wait Timer z Start Enable Register (ERMU_WTzSE) (z=0-3).....            | 1914        |
| 47.5.15 Error Source Status j Register (ERMU_ESSj) (j=0-1).....                 | 1915        |
| 47.5.16 Error Source Status Clear j Register (ERMU_ESSCj) (j=0-1).....          | 1915        |
| 47.5.17 Pseudo-error Source Trigger Register (ERMU_PETj) (j=0-1).....           | 1916        |
| 47.5.18 Reset Enable j Register (ERMU_REj) (j=0-1).....                         | 1916        |
| 47.5.19 Low Priority Interrupt Enable j Register (ERMU_LPIEj) (j=0-1).....      | 1917        |
| 47.5.20 High Priority Interrupt Enable j Register (ERMU_HPIEj) (j=0-1).....     | 1917        |
| 47.5.21 Count Clock Prescaler Register (ERMU_CCPS).....                         | 1918        |
| <b>48 Debug Controller (DBGC).....</b>                                          | <b>1919</b> |
| 48.1 Introduction.....                                                          | 1919        |
| 48.2 Functional Description.....                                                | 1919        |
| 48.2.1 Function Block Diagram.....                                              | 1919        |
| 48.2.2 Reference Documentation.....                                             | 1920        |
| 48.2.3 SWJ-DP Debug Port (SWD and JTAG).....                                    | 1920        |
| 48.2.4 Pin Arrangement and Debug Port Pins.....                                 | 1921        |
| 48.2.5 SW Debug Port-SW Protocol Overview.....                                  | 1922        |
| 48.2.6 TPIU (Trace Port Interface Unit).....                                    | 1923        |
| 48.3 Register Description.....                                                  | 1926        |
| 48.3.1 Register List.....                                                       | 1926        |
| 48.3.2 Chip Identification Register (CHIPID).....                               | 1927        |
| 48.3.3 DBG Status Register (MCUDBGSTAT).....                                    | 1927        |
| 48.3.4 Peripheral Debug Stop Control Register (MCUSTPCTL).....                  | 1928        |
| 48.3.5 Debug Component Trace Control Register (MCUTRACECTL).....                | 1931        |
| 48.3.6 Peripheral Debug Stop Control Register 2 (MCUSTPCTL2).....               | 1932        |
| <b>A Glossary.....</b>                                                          | <b>1934</b> |
| <b>Revision History .....</b>                                                   | <b>1935</b> |

## List of Figures

|             |                                                                                 |     |
|-------------|---------------------------------------------------------------------------------|-----|
| Figure 2-1  | QSPI Address Space Allocation.....                                              | 56  |
| Figure 3-1  | Bus Architecture Diagram.....                                                   | 62  |
| Figure 4-1  | Power-on Reset Timing Diagram.....                                              | 66  |
| Figure 4-2  | NRST Reset Timing Diagram.....                                                  | 67  |
| Figure 4-3  | Brown-out Reset Timing Diagram.....                                             | 67  |
| Figure 4-4  | Programmable Voltage Detection 1 Reset Timing Diagram.....                      | 68  |
| Figure 4-5  | Programmable Voltage Detection 2 Reset Timing Diagram.....                      | 68  |
| Figure 4-6  | Watchdog and Special Watchdog Reset Timing Diagram.....                         | 69  |
| Figure 4-7  | Power-off Wake-up Reset Timing Diagram.....                                     | 69  |
| Figure 4-8  | Software Reset Timing Diagram.....                                              | 69  |
| Figure 4-9  | MPU Error Reset Timing Diagram.....                                             | 70  |
| Figure 4-10 | RAM ECC Reset Timing Diagram.....                                               | 70  |
| Figure 4-11 | FLASH ECC Reset Timing Diagram.....                                             | 70  |
| Figure 4-12 | ERMU Reset Timing Diagram.....                                                  | 71  |
| Figure 4-13 | Clock Frequency Error Reset Timing Diagram.....                                 | 71  |
| Figure 4-14 | XTAL Error Reset Timing Diagram.....                                            | 71  |
| Figure 4-15 | Cortex-M4 Lockup Reset Timing Diagram.....                                      | 72  |
| Figure 4-16 | Module Function Reset.....                                                      | 72  |
| Figure 5-1  | Clock System Block Diagram.....                                                 | 90  |
| Figure 5-2  | Clock Frequency Measurement Block Diagram.....                                  | 91  |
| Figure 5-3  | External High Speed Oscillator Connection Example.....                          | 94  |
| Figure 5-4  | External Clock Input Connection Example.....                                    | 94  |
| Figure 5-5  | External High-speed Oscillator Fault Detection Example.....                     | 95  |
| Figure 5-6  | System Clock Selected as XTAL, Example of Detecting XTAL Oscillation Fault..... | 96  |
| Figure 5-7  | External Low-speed Oscillator Connection Example.....                           | 97  |
| Figure 5-8  | Clock Source Switching Flowchart.....                                           | 100 |
| Figure 5-9  | Clock Division Switching Flowchart.....                                         | 101 |
| Figure 5-10 | Clock Frequency Measurement Timing Diagram.....                                 | 102 |
| Figure 6-1  | Power Supply Configuration Diagram.....                                         | 152 |
| Figure 6-2  | Battery Backup Domain Power Switching Diagram.....                              | 153 |
| Figure 6-3  | Power-on Reset, Power-off Reset Waveforms.....                                  | 154 |
| Figure 6-4  | Brown-out Reset Waveform.....                                                   | 154 |
| Figure 6-5  | PVD1 Interrupt/Reset Block Diagram.....                                         | 155 |
| Figure 6-6  | PVD2 Interrupt/Reset Block Diagram.....                                         | 156 |
| Figure 6-7  | Power Monitor 1 Interrupt Timing Diagram.....                                   | 157 |
| Figure 6-8  | Power Monitor 1 Reset Timing Diagram.....                                       | 157 |
| Figure 6-9  | Power Monitor 2 Interrupt Timing Diagram.....                                   | 158 |
| Figure 6-10 | Power Monitor 2 Reset Timing Diagram.....                                       | 158 |
| Figure 6-11 | Internal Voltage Sampling Diagram.....                                          | 159 |
| Figure 6-12 | PTWKn Structure Diagram.....                                                    | 169 |
| Figure 8-1  | Flash Address Distribution.....                                                 | 221 |
| Figure 8-2  | Flash Address Distribution for 2MBytes Products.....                            | 230 |
| Figure 8-3  | Boot Swap Activation 1.....                                                     | 230 |
| Figure 8-4  | Boot Swap Activation 2.....                                                     | 230 |
| Figure 9-1  | Error Injection Diagram for SRAM 39-bit.....                                    | 270 |
| Figure 9-2  | Error Injection Diagram for CACHE RAM 137-bit.....                              | 271 |
| Figure 10-1 | Port Basic Structure Diagram.....                                               | 303 |
| Figure 11-1 | Interrupt System Block Diagram.....                                             | 347 |
| Figure 11-2 | Interrupt Request/Event Input Selection.....                                    | 349 |
| Figure 11-3 | Digital Filter Operation Diagram (taking NFSEL=0x02 as an example).....         | 350 |

|              |                                                                                              |     |
|--------------|----------------------------------------------------------------------------------------------|-----|
| Figure 12-1  | AOS Module Block Diagram.....                                                                | 371 |
| Figure 12-2  | PLU Block Diagram.....                                                                       | 374 |
| Figure 13-1  | Schematic Diagram of Partial Memory Access Permissions.....                                  | 400 |
| Figure 13-2  | Schematic Diagram of only Prohibiting Access to Part of Space.....                           | 400 |
| Figure 14-1  | KEYSCAN System Block Diagram.....                                                            | 437 |
| Figure 14-2  | Keyboard Scan Function Diagram.....                                                          | 438 |
| Figure 15-1  | CTC Function Block Diagram.....                                                              | 444 |
| Figure 15-2  | CTC Calibration Diagram.....                                                                 | 446 |
| Figure 16-1  | DMA Architecture Diagram.....                                                                | 455 |
| Figure 16-2  | Chain Transmission Diagram.....                                                              | 458 |
| Figure 16-3  | Schematic Diagram of NonSequence Address Transfer (Taking source address as an example)..... | 459 |
| Figure 16-4  | Schematic Diagram of NonSequence Reset.....                                                  | 461 |
| Figure 16-5  | Application Example 1: Memory-to-Memory Transfer.....                                        | 463 |
| Figure 16-6  | Application Example 2: Memory-to-Peripheral Transfer.....                                    | 464 |
| Figure 17-1  | CMP Function Block Diagram.....                                                              | 502 |
| Figure 17-2  | Voltage Comparison Diagram.....                                                              | 504 |
| Figure 17-3  | Window Compare Diagram.....                                                                  | 505 |
| Figure 17-4  | Blank Window Output Diagram.....                                                             | 506 |
| Figure 18-1  | ADC Block Diagram.....                                                                       | 519 |
| Figure 18-2  | Channel Mapping Diagram.....                                                                 | 521 |
| Figure 18-3  | Internal Analog Signal Selection.....                                                        | 522 |
| Figure 18-4  | Sequence A Single Scan Mode.....                                                             | 523 |
| Figure 18-5  | Continuous Scan.....                                                                         | 523 |
| Figure 18-6  | Data Buffer Mode.....                                                                        | 524 |
| Figure 18-7  | Dual Sequence Scan Mode (Sequence A Restarts from Interrupted Channel).....                  | 526 |
| Figure 18-8  | Dual Sequence Scan Mode (Sequence A Restarts from First Channel).....                        | 526 |
| Figure 18-9  | Analog Watchdog Protected Area (Comparative Mode).....                                       | 527 |
| Figure 18-10 | ADC Conversion Time Diagram.....                                                             | 528 |
| Figure 18-11 | Conversion Action When Averaging Function is Enabled.....                                    | 529 |
| Figure 18-12 | PGA and SH Channel Diagram for ADC1 and ADC2.....                                            | 531 |
| Figure 18-13 | Dedicated Sample Hold Circuit for Channels Enabled.....                                      | 532 |
| Figure 18-14 | Single Parallel Trigger Mode (Three ADCs).....                                               | 533 |
| Figure 18-15 | Single Delay Trigger Mode (Three ADCs).....                                                  | 534 |
| Figure 18-16 | Loop Parallel Trigger Mode (Three ADCs).....                                                 | 535 |
| Figure 18-17 | Loop Delay Trigger Mode (Two ADCs).....                                                      | 536 |
| Figure 18-18 | Loop Delay Trigger Mode (Three ADCs).....                                                    | 536 |
| Figure 18-19 | ADC Interrupt and Event Output Timing.....                                                   | 537 |
| Figure 19-1  | DAC Conversion Channel Block Diagram.....                                                    | 571 |
| Figure 19-2  | DAC Conversion Diagram.....                                                                  | 572 |
| Figure 19-3  | ADC Conversion Priority Mode Action Schematic Diagram.....                                   | 573 |
| Figure 20-1  | OTS Function Block Diagram.....                                                              | 582 |
| Figure 21-1  | Timer6 Basic Block Diagram.....                                                              | 592 |
| Figure 21-2  | Sawtooth Waveform (Counting Up).....                                                         | 593 |
| Figure 21-3  | Triangle Waveform.....                                                                       | 593 |
| Figure 21-4  | Compare Output Action.....                                                                   | 594 |
| Figure 21-5  | Capture Input Action.....                                                                    | 594 |
| Figure 21-6  | Hardware Refresh Action.....                                                                 | 596 |
| Figure 21-7  | Digital Filtering Function of Capture Input Ports.....                                       | 596 |
| Figure 21-8  | Software Synchronization Action.....                                                         | 598 |
| Figure 21-9  | Hardware Synchronization Action.....                                                         | 600 |
| Figure 21-10 | Pulse Width Measurement.....                                                                 | 601 |
| Figure 21-11 | Period Measurement.....                                                                      | 601 |

|              |                                                                                                     |     |
|--------------|-----------------------------------------------------------------------------------------------------|-----|
| Figure 21-12 | Timing Diagram of Compare Output in Single Buffer Mode.....                                         | 603 |
| Figure 21-13 | Capture Input Timing in Double Buffer Mode.....                                                     | 604 |
| Figure 21-14 | Count Buffer Operation in Sawtooth Mode.....                                                        | 605 |
| Figure 21-15 | Count Buffer Operation 1 in Triangle Mode.....                                                      | 606 |
| Figure 21-16 | Count Buffer Operation 2 in Triangle Mode.....                                                      | 606 |
| Figure 21-17 | Single-Edge Aligned Independent PWM.....                                                            | 607 |
| Figure 21-18 | Double-Edge Symmetrical independent PWM.....                                                        | 608 |
| Figure 21-19 | Software-Set GCMBR Complementary PWM Output.....                                                    | 609 |

## 1 Product Introduction

HC32A4A8 Series is a high-performance MCU with maximum operating 240MHz frequency based on 32-bit ARM® Cortex®-M4 Microcontroller. The Cortex-M4 core integrates an FPU and DSP for single-precision floating-point operations, supporting all ARM single-precision data processing instructions, data types, and full DSP instruction sets. The core integrates MPU and DMAC-dedicated MPU for system security.

HC32A4A8 Series integrates high-speed on-chip memory, including up to 2MB Flash and 512KB SRAM, both with ECC support. It integrates a Flash access acceleration unit to achieve single-cycle program execution by the CPU on Flash. A polling bus matrix allows multiple bus masters to access memory and peripherals simultaneously, enhancing performance. Bus masters include CPU, DMA, USB-dedicated DMA, and ETHMAC-dedicated DMA. In addition to the bus matrix, it supports peripheral-to-peripheral data transfer, basic arithmetic operations, and event triggering, significantly reducing CPU workload.

HC32A4A8 Series integrates rich peripheral functions. Includes 3 independent 12-bit 2.5Msps ADCs, 4 programmable gain amplifiers (PGA), 4 12-bit DACs, 4 high-speed comparators (CMP), 8 multifunction PWM Timers (Timer6) supporting 16-channel complementary PWM output, 3 motor PWM Timers (Timer4) supporting 18-channel complementary PWM output, 12 16-bit general-purpose Timers (TimerA) with 6-channel 3-phase quadrature encoder input and 48-channel Duty independently configurable PWM outputs, 22 serial interfaces (I2C/USART/SPI), 1 QSPI, 4 CAN, 4 I2S with audio PLL, 2 SDIOs, 1 ETHMAC, USBFS Controller with built-in PHY and USBHS Controller, 1 external bus controller (NFC, SMC, DMC), 1 DVP, 1 MAU, 4 FMACs, 1 SKE, 1 PKE, 1 ERMU, 1 HSM Light-Mid.

HC32A4A8 Series supports wide voltage (1.8-3.63V), wide temperature (-40-125°C), and multiple low-power modes. Supports fast wake-up from low-power modes: 2μs from STOP mode, 25μs from Power-down mode.

### Typical Application

HC32A4A8 Series is available in 100-pin, 144-pin, and 176-pin LQFP package, designed for automotive electronics (e.g., T-Box, BMS controllers, gateways, vehicle lighting control).

### About This Manual

This manual describes the chip's functionalities, operational guidelines, and usage methods. For detailed chip specifications, refer to the corresponding "Datasheet".

## 2 Memory Mapping

### 2.1 Memory Mapping

This MCU supports a 4GB linear address space, with addresses from 0x00000000 to 0xFFFFFFFF, including programs and data. Please refer to the table below for detailed memory mapping.

Table 2-1 Memory Mapping

| Memory Classification <sup>(2)</sup> |                                 | Start Address <sup>(1)</sup> | End Address <sup>(1)</sup> | Space Size | Module <sup>(3)</sup> | Protection <sup>(4)</sup> | Description                         |
|--------------------------------------|---------------------------------|------------------------------|----------------------------|------------|-----------------------|---------------------------|-------------------------------------|
| System                               | -                               | 0xE0100000                   | 0xFFFFFFFF                 | 511MB      | Reserved              | -                         | Custom space                        |

**Note**

1. Please refer to the "ARM Cortex-M4 Processor Technical Reference Manual Revision: r0p1".
2. For bus descriptions, please refer to the relevant descriptions in the "Bus Architecture (BUS) " chapter.
3. Reserved: Accessing the bus will cause a bus error.  
BLANK: Write access has no effect; reading returns 0.
4. Modules with protection functions only support access in CPU privileged mode when the protection function is active. For specific registers and descriptions, refer to the relevant content in the "Memory Protection Unit (MPU)" chapter.

## 2.2 External Space Mapping

The QSPI space is divided into two segments, including 64MB of QSPI register space and 64MB of external QSPI device space. Please refer to the figure below for the allocation relationship.

Figure 2-1 QSPI Address Space Allocation

## 2.3 Bit Segment Space

Cortex-M4 memory mapping includes two bit segment regions. These regions map each word in the memory alias region to the corresponding bit in the memory bit segment region. When you write to an alias region, it is equivalent to a read-modify-write operation on the target bit of the bit band region.

In this MCU, peripheral registers and SRAM are mapped to a bit segment region, enabling read and write operations on individual bit segments. These operations are only applicable to Cortex-M4 access and are disabled for other bus master interfaces (e.g., DMA).

## 2.4 Address Remapping

This MCU provides a memory address remapping function with two remapping addresses available for free configuration, using MMF\_REMCR0 and MMF\_REMCR1 to configure the remapping target address, which can be either the main flash address or the SRAMH address.

- Remapping Address 0:  
0x02000000-0x02080000 (depending on the set remapping space size through MMF\_REMCR0.RMSIZE[4:0] )
- Remapping Address 1:  
0x02080000-0x02100000 (depending on the set remapping space size through MMF\_REMCR1.RMSIZE[4:0])

When the remapping function is enabled (MMF\_REMCR0.EN=1 or MMF\_REMCR1.EN=1), the address correspondence table is as follows:

**Table 2-2 Target Address Configuration Main Flash Example (MMF\_REMCR0.EN=1 or MMF\_REMCR1.EN=1)**

| Register Setting                                       | Remapping Address (CPU Address-CPUADDR[31:0]) | Remapping Target Address (Main Flash Address) |                                       |               |
|--------------------------------------------------------|-----------------------------------------------|-----------------------------------------------|---------------------------------------|---------------|
|                                                        |                                               | Upper 12 Bits                                 | Middle 6 Bits                         | Lower 14 Bits |
| REMCR0.RMSIZE[4:0]=0b01110<br>(Remapping Space: 16KB)  | 0x02000000-0x02003FFF                         | All 0                                         | REMCR0.RMTADDR[5:0]                   | CPUADDR[13:0] |
| REMCR0.RMSIZE[4:0]=0b01111<br>(Remapping Space: 32KB)  | 0x02000000-0x02007FFF                         | All 0                                         | REMCR0.RMTADDR[4:0]<br>CPUADDR[14]    | CPUADDR[13:0] |
| REMCR1.RMSIZE[4:0]=0b10000<br>(Remapping Space: 64KB)  | 0x02080000-0x02087FFF                         | All 0                                         | REMCR1.RMTADDR[3:0]<br>CPUADDR[15:14] | CPUADDR[13:0] |
| REMCR1.RMSIZE[4:0]=0b10001<br>(Remapping Space: 128KB) | 0x02080000-0x0208FFFF                         | All 0                                         | REMCR1.RMTADDR[2:0]<br>CPUADDR[16:14] | CPUADDR[13:0] |

**Table 2-3 Target Address Configuration SRAMH Example (MMF\_REMCR0.EN=1 or MMF\_REMCR1.EN=1)**

| Register Setting                                     | Remapping Address (CPU Address-CPUADDR[31:0]) | Remapping Target Address (SRAM Address) |                                     |               |
|------------------------------------------------------|-----------------------------------------------|-----------------------------------------|-------------------------------------|---------------|
|                                                      |                                               | Upper 3 Bits                            | Middle 17 Bits                      | Lower 12 Bits |
| REMCR0.RMSIZE[4:0]=0b01100<br>(Remapping Space: 4KB) | 0x02000000-0x02000FFF                         | All 0                                   | REMCR0.RMTADDR[16:0]                | CPUADDR[11:0] |
| REMCR0.RMSIZE[4:0]=0b01101<br>(Remapping Space: 8KB) | 0x02000000-0x02001FFF                         | All 0                                   | REMCR0.RMTADDR[15:0]<br>CPUADDR[12] | CPUADDR[11:0] |
| REMCR1.RMSIZE[4:0]=0b01100<br>(Remapping Space: 4KB) | 0x02080000-0x02080FFF                         | All 0                                   | REMCR1.RMTADDR[16:0]                | CPUADDR[11:0] |
| REMCR1.RMSIZE[4:0]=0b01101<br>(Remapping Space: 8KB) | 0x02080000-0x02081FFF                         | All 0                                   | REMCR1.RMTADDR[15:0]<br>CPUADDR[12] | CPUADDR[11:0] |

Example:

- Using the remapping address 0 function, set the source address to the main flash address 0x00008000, with a remapping space of 32K; the register MMF\_REMCR0 needs to be set to 0x8000800F.
- Using the remapping address 1 function, set the source address to SRAMH address 0x1FFFE000, with a remapping space of 16K; the register MMF\_REMCR1 needs to be set to 0x9FFFE00E.

#### Notice

The start address of the source address should be set to an integer multiple of the remapping space.

## 2.5 Register Description

### 2.5.1 Register List

Base address: 0x40010500

Table 2-4 Memory Mapping Register Offset

| Offset       | Register   | Description                  | Width |
|--------------|------------|------------------------------|-------|
| 0x0000       | MMF_REMPRT | Access Protection Register   | 32    |
| 0x0004+0x4*x | MMF_REMCrx | Remapping Register x (x=0-1) | 32    |

## 2.5.2 Access Protection Register (MMF\_REMPRT)

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 0x0000 | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15         | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## 3 Bus Architecture (BUS)

### 3.1 Introduction

The main system consists of a 32-bit multi-layer AHB bus matrix, enabling the interconnection of the following host buses and slave buses:

- Host bus
  - ▶ Cortex-M4 core CPU-I bus, CPU-D bus, CPU-S bus
  - ▶ System DMA\_1 bus, System DMA\_2 bus
  - ▶ USBFS\_DMA bus
  - ▶ USBHS\_DMA bus
  - ▶ ETHMAC\_DMA bus
- Slave bus
  - ▶ Flash ICODE bus
  - ▶ Flash DCODE bus
  - ▶ Flash MCODE bus (The bus through which non-CPU hosts access the Flash memory)
  - ▶ High-speed SRAMH (SRAMH 128KB) bus
  - ▶ System SRAM (SRAM1 128KB) bus
  - ▶ System SRAM (SRAM2 128KB) bus
  - ▶ System SRAM (SRAM3 96KB, SRAM4 32KB, Ret SRAM 4KB) bus
  - ▶ APB1 peripheral bus (AOS/EMB/Timer6/SPI/USART/I2S/EFM)
  - ▶ APB2 peripheral bus (Timer0/Timer2/TimerA/SPI/USART/I2S/CAN/MCAN)
  - ▶ APB3 peripheral bus (ADC/DAC/TRNG)
  - ▶ APB4 peripheral bus (FCG/CMU/FCM/ERMU/WDT/SWDT/CMP/PWC/CTC/OTS/RTC/VBAT/WKTM/I2C)
  - ▶ APB5 peripheral bus (Timer4/TimerA)
  - ▶ AHB1 peripheral bus (MPU/RAMIF/KEYSCAN/INTC/DCU/GPIO/DMA/CMU/DVP/MAU/FMAC)
  - ▶ AHB2 peripheral bus (CAN/SDIOC/USBFS)
  - ▶ AHB3 peripheral bus (SDIOC/ETHMAC)
  - ▶ AHB4 peripheral bus (HASH/CRC/CAN/USBHS/PKE/SKE)
  - ▶ AHB5 peripheral bus (SMC/DMC/SMCR/DMCR/NFC/QSPI)

With the bus matrix, efficient concurrent access from host buses to slave buses can be achieved.

## 3.2 Bus Architecture

Figure 3-1 Bus Architecture Diagram

The bus matrix manages access arbitration between host buses. Arbitration uses a round-robin scheduling algorithm.

- CPU-I bus

Cortex-M4 Core Command Bus: The CPU fetches instructions through this bus. Access targets: Flash and SRAMH containing code.

- CPU-D bus  
Cortex-M4 Core Data Bus: The CPU performs immediate number loading and debug access through this bus. Access targets: Flash and SRAMH containing code or data.
- CPU-S bus  
Cortex-M4 Core System Bus: The CPU accesses peripherals or system SRAM through this bus. It can also fetch instructions and immediate numbers through this bus (though less efficient than through the CPU-I bus and CPU-D bus). Access targets: SRAM1/SRAM2/SRAM3/SRAM4/Ret SRAM, all peripherals, and external extended space.
- DMA\_1 bus, DMA\_2 bus  
System DMA\_1/system DMA\_2 dedicated bus, DMA\_1/DMA\_2 accesses data memory and peripherals through this bus. The access objects are Flash/SRAMH/SRAM1/SRAM2/SRAM3/SRAM4/Ret SRAM, all peripherals, and external extended space.
- USBFS\_DMA bus  
DMA dedicated bus for USBFS, through which USBFS accesses all memory spaces. Access targets include Flash/SRAMH/SRAM1/SRAM2/SRAM3/SRAM4/Ret SRAM, and external extended space.
- USBHS\_DMA bus  
USBHS DMA dedicated bus, allowing USBHS to access all memory spaces via this bus. Access targets include Flash/SRAMH/SRAM1/SRAM2/SRAM3/SRAM4/Ret SRAM, and external extended space.
- ETHMAC\_DMA bus  
ETHMAC DMA dedicated bus, allowing ETHMAC to access all memory spaces via this bus. Access targets include Flash/SRAMH/SRAM1/SRAM2/SRAM3/SRAM4/Ret SRAM, and external extended space.

### 3.3 Bus Function

The bus is responsible for the host's read and writes access to the slave computer. When the operating frequency of the host module is higher than that of the slave module (such as CPU-S accessing RTC), the bus will automatically perform frequency reduction synchronization processing. When the operating frequency of the host module is lower than that of the slave module (such as USBFS\_DMA accessing SRAMH), the bus automatically performs up-frequency synchronization processing.

Through the bus matrix, when the access targets of different host buses do not conflict, each access can be carried out simultaneously. For example, CPU-I accesses Flash, CPU-D accesses SRAMH, CPU-S accesses APB peripherals, DMA\_1 accesses SRAM1, DMA\_2 accesses SRAM2, USBFS\_DMA accesses the external expansion space of AHB5, and these accesses can be performed simultaneously.

## 4 Reset Module Unit (RMU)

### 4.1 Introduction

The chip is configured with 16 reset modes:

- Power-on Reset (POR)
- NRST pin Reset (NRST)
- Brown-out Reset (BOR)
- Programmable Voltage Detect 1 Reset (PVD1R)
- Programmable Voltage Detect 2 Reset (PVD2R)
- Watchdog Reset (WDTR)
- Special Watchdog Reset (SWDTR)
- Power-down Wake-up Reset (PDRST)
- Software Reset (SRST)
- MPU Error Reset (MPUR)
- RAMECC Reset (RAMECCR)
- FLASHECC Reset (FLASHECCR)
- ERMU Reset (ERMUR)
- Clock Frequency Error Reset (CKFER)
- XTAL Error Reset (XTALER)
- Cortex-M4 Lockup Reset (LKUPR)

### 4.2 Functional Description

#### 4.2.1 Reset Mode and Reset Flag Bit

The reset mode and generating conditions are shown in the following table.

**Table 4-1 Reset Mode and Generating Conditions**

| Reset Mode                             | Generating Condition                                                                                                                    |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Power-on Reset                         | VCC powered on                                                                                                                          |
| NRST Pin Reset                         | NRST pin input low level                                                                                                                |
| Brown-out Reset                        | VCC voltage drops below VBOR voltage                                                                                                    |
| Programmable Voltage Detection 1 Reset | VCC voltage drops below PVD1 voltage                                                                                                    |
| Programmable Voltage Detection 2 Reset | VCC voltage drops below PVD2 voltage                                                                                                    |
| Watchdog Reset                         | Watchdog timer generates a refresh error or an overflow error                                                                           |
| Special Watchdog Reset                 | Refresh error or overflow error occurred in special watchdog                                                                            |
| Power-down Wake-up Reset               | By setting the reset generated by the Power-down mode, the core wakes up from the reset state after the Power-down wake-up event occurs |
| Software Reset                         | Set the reset register bit (ARM register AIRCR.SYSRESETREQ bit)                                                                         |
| MPU Error Reset                        | Reset generated by MPU access error                                                                                                     |

| Reset Mode                     | Generating Condition                                                                                                                                                      |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RAM ECC Reset                  | Reset generated when ECC error occurs in RAM                                                                                                                              |
| FLASH ECC Reset                | Reset generated when ECC error occurs in FLASH                                                                                                                            |
| ERMU Reset                     | When a reset request is issued to the ERMU                                                                                                                                |
| Clock frequency Error Reset    | When the clock frequency monitoring function (FCM) detects a clock period error                                                                                           |
| XTAL Error Reset               | Resetting of external high-speed oscillator abnormal shock                                                                                                                |
| Cortex-M4 Lockup Reset (LKUPR) | When Cortex-M4 encounters a serious exception, it will stop its PC pointer at the current address and lock it, and reset the entire chip after a few clock period delays. |

When a reset occurs, the chip will set the corresponding reset flag according to the reset method, and the reset flag is as shown. For example, pin reset occurs, pin reset flag bit PINRF is set to 1, PINRF can be reset by writing CLRF after PINRF is set.

Table 4-2 Reset Mode and Reset Flag

| Reset Flag                                                     | Reset mode     |           |                 |                           |                           |                |                        |                          |                |                 |               |                 |            |                             |                  |
|----------------------------------------------------------------|----------------|-----------|-----------------|---------------------------|---------------------------|----------------|------------------------|--------------------------|----------------|-----------------|---------------|-----------------|------------|-----------------------------|------------------|

## 4.2.2 Reset Timing

### 4.2.2.1 Power-on Reset

Power-on reset is an internal reset caused by the power-on reset circuit, and the timing is as follows. Power-on reset occurs when the NRST pin is connected to the power supply at a high level. After a certain period of time ( $T_{RSTPOR}$ ) after the VCC voltage is higher than the power-on reset voltage  $V_{POR}$ , the internal reset of the chip is released, and the CPU starts to execute the code. When generating power-on reset, power-on reset flag RMU\_RSTF0.PORF is set. For detailed instructions on power-on reset, see ["Power-on/Power-off Reset Action Description"](#) in the "Power Control (PWC)" chapter.

Figure 4-1 Power-on Reset Timing Diagram

#### 4.2.2.2 NRST Pin Reset

Pin reset is caused by the NRST pin being driven to a low level. The reset timing is shown in the figure below. After the NRST pin maintains a low level above the  $T_{NRST}$  width, after a certain internal reset time ( $T_{INRST}$ ), the internal reset is released.

When a NRST pin reset is generated, the pin reset flag `RMU_RSTF0.PINRF` is set.

Figure 4-2 NRST Reset Timing Diagram

#### 4.2.2.3 Brown Out Reset

Brown-out reset is an internal reset caused by the voltage monitoring circuit, and the timing is shown in the figure below. After the undervoltage is set as reset enable through the ICG register, if the VCC voltage is lower than the monitoring voltage  $V_{BOR}$ , `RMU_RSTF0.BORF` will be set. When the VCC voltage is higher than the monitoring voltage  $V_{BOR}$ , the reset will be released after the  $V_{BOR}$  reset time ( $T_{RSTBOR}$ ).

For the reset setting of brownout, please refer to the "[Brown-out Reset \(BOR\) Description](#)" in the "Power Control (PWC)" chapter.

Figure 4-3 Brown-out Reset Timing Diagram

#### 4.2.2.4 Programmable Voltage Detection 1 Reset, Programmable Voltage Detection 2 Reset

Reset caused by the voltage monitor circuit when Programmable Voltage Detection 1 and Programmable Voltage Detection 2 are reset.

When the VCC voltage is lower than the monitoring voltage of the programmable voltage detection 1, a programmable voltage detection 1 reset may be generated according to the setting, and `RMU_RSTF0.PVD1RF` is set. When the VCC voltage is higher than the monitoring voltage of programmable voltage detection 1, the reset will be released after the reset time of PVD1 ( $T_{IPVD1}$ ).

Figure 4-4 Programmable Voltage Detection 1 Reset Timing Diagram

When the VCC voltage is lower than the monitoring voltage of the programmable voltage detection 2, according to the setting, a programmable voltage detection 2 reset may be generated and RMU\_RSTF0.PVD2RF is set. When the VCC voltage is higher than the monitoring voltage of programmable voltage detection 2, the reset will be released after the reset time of PVD2 ( $T_{IPVD2}$ ).

Figure 4-5 Programmable Voltage Detection 2 Reset Timing Diagram

For the reset settings of programmable voltage detection 1 and programmable voltage detection 2, see "[Programmable Voltage Detection 1 \(PVD1\)](#), [Programmable Voltage Detection 2 \(PVD2\)](#)" in the "Power Control (PWC)" chapter.

#### 4.2.2.5 Watchdog Reset, Special Watchdog Reset

The watchdog reset is an internal reset caused by the watchdog timer, and the special watchdog reset is an internal reset caused by the special watchdog timer. The reset timing is as follows.

After the watchdog reset is set to be active, the watchdog reset will be generated when the watchdog timer underflows or the write operation is not performed during the refresh period. A watchdog reset sets RMU\_RSTF0.WDRF. After the watchdog reset is generated, the chip is released from reset after the internal reset time  $T_{RIPT}$ .

After the special watchdog reset is set to be active, the watchdog reset will be generated when the special watchdog timer underflows or the write operation is not performed during the refresh period. Special

watchdog reset RMU\_RSTF0.SWDRF setup. After generating special watchdog reset, after internal reset time  $T_{RIPT}$ , the chip is released.

For details on watchdog reset and special watchdog reset, see the relevant description in the "Watchdog Timer (WDT/SWDT) " chapter.

Figure 4-6 Watchdog and Special Watchdog Reset Timing Diagram

#### 4.2.2.6 Power-down Wake-up Reset

Power-down wake-up reset is an internal reset generated when the chip executes the WFI command when PWC\_PWRC0.PWDN is set to 1, enters Power-down mode, and releases Power-down mode through a Power-down mode wake-up event. The timing is as follows. After the Power-down mode is released and the return time  $T_{IPDx}$  ( $x=1, 2, 3, 4$ ) has elapsed, the Power-down wake-up reset is released. The return time varies according to the specific Power-down mode set, the minimum is in Power-down mode 1, and the maximum is in Power-down mode 3.

For details about Power-down wake-up reset, see "Power-down Mode" in the "Power Control (PWC) " chapter.

Figure 4-7 Power-off Wake-up Reset Timing Diagram

#### 4.2.2.7 Software Reset

A software reset is generated by writing the AIRCR.SYSRESETREQ bit of ARM register. When generating software reset, RMU\_RSTF0.SWRF bit is set. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

Figure 4-8 Software Reset Timing Diagram

#### 4.2.2.8 MPU Error Reset

The MPU error reset sets `RMU_RSTF0.MPUERF`, and the timing is shown below. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the settings of MPU error reset, see the relevant description in the "Memory Protection Unit (MPU) " chapter.

Figure 4-9 MPU Error Reset Timing Diagram

#### 4.2.2.9 RAM ECC Reset

When a RAM ECC check error occurs, a RAM ECC reset may occur according to the settings. The reset timing is as follows. A RAM ECC reset sets `RMU_RSTF0.RAECRF`. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the RAM ECC reset settings, please refer to the relevant description in the "Built-in SRAM (SRAM) " chapter.

Figure 4-10 RAM ECC Reset Timing Diagram

#### 4.2.2.10 FLASH ECC Reset

When an error occurs in the FLASH ECC check, a FLASH ECC reset occurs, and the timing is as follows. A FLASH ECC reset sets `RMU_RSTF0.FLECRF`. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the setting of FLASH ECC reset, please refer to the relevant description in the "Embedded Flash Memory (EFM) " chapter.

Figure 4-11 FLASH ECC Reset Timing Diagram

#### 4.2.2.11 ERMU Reset

When ERMU is reset, ERMU reset is generated, and the timing is as follows. An ERMU reset sets `RMU_RSTF0.ERMURF`. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the ERMU reset settings, please refer to the relevant description in the "Error Management Unit (ERMU)" chapter.

Figure 4-12 ERMU Reset Timing Diagram

#### 4.2.2.12 Clock Frequency Error Reset

When the FCM module built into the chip detects an abnormal clock frequency, it can generate a clock frequency error reset according to the settings. The reset timing is as follows. Clock frequency error reset sets `RMU_RSTF0.CKFERF`. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the setting of clock frequency error reset, refer to "[Clock Frequency Measurement](#)" in the "Clock Module Unit (CMU)" chapter.

Figure 4-13 Clock Frequency Error Reset Timing Diagram

#### 4.2.2.13 XTAL Error Reset

When the chip's oscillation stop detection is enabled and reset is also enabled, if an abnormal stop of the external high-speed oscillator occurs, the XTAL error reset will be generated, and the `RMU_RSTF0.XTALERF` flag will be set. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

For the setting of XTAL error reset, refer to "[External High-speed Oscillator Fault Detection](#)" in the "Clock Module Unit (CMU)" chapter.

Figure 4-14 XTAL Error Reset Timing Diagram

#### 4.2.2.14 Cortex-M4 Lockup Reset

When Cortex-M4 encounters a serious exception, it will stop its PC pointer at the current address, lock it, and reset the entire chip after a delay of several clock periods. The timing is shown below. Cortex-M4 Lockup reset sets `RMU_RSTF0.LKUPRF`. After the internal reset time  $T_{RIPT}$ , the chip is de-reset.

Cortex-M4 Lockup reset can only be used after `RMU_PRSTCR0.LKUPREN` is set.

Figure 4-15 Cortex-M4 Lockup Reset Timing Diagram

### 4.2.3 Reset Mode Judgment

The reset mode can be judged according to the reset flag of RMU\_RSTF0. Multiple reset flags may occur when two or more resets occur simultaneously. Multiple resets occur when the RMU\_RSTF0.MULTIRF bit is 1. After reading RMU\_RSTF0, all reset flags can be cleared to 0 by setting the CLRFB bit. After setting and clearing RMU\_RSTF0, wait at least 6 CPU clock periods before reading the RMU\_RSTF0 register again.

### 4.2.4 Module Function Reset

In addition to the above-mentioned chip reset methods, the product also configures functional reset registers RMU\_FRST0-3 for each peripheral module. Writing 0 to the corresponding bit of RMU\_FRST can reset the function of the corresponding module. After RMU\_FRST is written to 0, it will be automatically set to 1 after 2 rising edge of peripheral module clock.

Figure 4-16 Module Function Reset

### 4.2.5 Reset Condition

Table 4-3 Reset Conditions for Each Module

| Modules | Register                                             | Reset Source                                        |

## 5 Clock Module Unit (CMU)

### 5.1 Introduction

The clock control unit provides a series of clock functions with different frequencies, including: an External High-speed Oscillator, an External Low-speed Oscillator, two PLL clocks, an Internal High-speed Oscillator, an Internal Medium-speed Oscillator, an Internal Low-speed Oscillator, a RTC Dedicated Internal Low-speed Oscillator, a dedicated Internal Low-speed Oscillator for SWDT, a Clock Prescaler, Clock Multiplexing, and Clock Gating Circuit.

The clock control unit also provides a clock frequency measurement function. The clock frequency measurement circuit (FCM) monitors and measures the measurement target clock using the measurement reference clock. An interrupt or reset occurs when the setting range is exceeded.

AHB, APB, and Cortex-M4 clocks are derived from the System Clock. The maximum operating clock frequency of the System Clock can reach 240MHz, with 6 selectable clock sources:

1. External High-speed Oscillator (XTAL)
2. External Low-speed Oscillator (XTAL32)
3. PLLH Clock (PLLH)
4. Internal High-speed Oscillator (HRC)
5. Internal Medium-speed Oscillator (MRC)
6. Internal Low-speed Oscillator (LRC)

For each clock source, it can be individually turned on and off when not in use to reduce power consumption.

SWDT has an independent clock source: the Dedicated Internal Low-speed Oscillator for SWDT (SWDTLRC). The Real Time Clock (RTC) uses the External Low-speed Oscillator, the RTC Dedicated Internal Low-speed Oscillator, or the XTAL fractional frequency division clock as the clock source. The 48MHz clock for USBFS can select the System Clock, PLLH, or PLLA as the clock source.

### 5.2 Features

Table 5-1 Clock Source Main Features

| Clock Source                           | Specifications                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| TPIUCLK  | Cortex-M4 Debug Tracker Clock                                                                                              | Maximum frequency 60MHz.<br>Configured by the CMU_TPIUCKCFGR.TPIUCKS bit.<br>Selectable system clock division: 1, 2, 4.                                                                                                                                    |
| ULPICKL  | USBHS HighSpeed Communication Clock                                                                                        | Frequency 60 MHz                                                                                                                                                                                                                                           |

| Clock   | Scope of Action   | Specifications                                                                                                                        |
|---------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| I2SnCLK | I2Sn (n=1-4)      | Maximum frequency 240MHz.<br>Configured by the CMU_I2SCKSEL register.<br>Selectable clocks: PLLAP, PLLAQ, PLLAR, PLLHQ, PLLHR, PCLK1. |
| TRNGCLK | TRNG Action Clock | The frequency is 1MHz.<br>Fixed at 8x division of MRC. Disable stopping the MRC clock when using the TRNG function.                   |

The following rules must be followed between clocks:

1. HCLK frequency  $\geq$  PCLK2, PCLK3, PCLK4 frequency
2. ETHMAC:
  - ETHMAC MII mode:
    - ▶ PCLK1 frequency > 2 times MII\_TX\_CLK/MII\_RX\_CLK frequency
    - ▶ HCLK frequency > PCLK1 frequency
  - ETHMAC RMII mode:
    - ▶ PCLK1 frequency > RMII\_REF\_CLK frequency
    - ▶ HCLK frequency > PCLK1 frequency
  - When ETHMAC is not in use:
    - ▶ HCLK frequency  $\geq$  PCLK1 frequency
3. NFC:
  - When NFC is in use: HCLK frequency > PCLK1 frequency
  - When NFC is not in use: HCLK frequency  $\geq$  PCLK1 frequency
4. PCLK0 frequency  $\geq$  PCLK1 frequency, PCLK0 frequency  $\geq$  PCLK3 frequency
5. HCLK frequency: PCLK0 frequency = N: 1, 1: N
6. PCLK2 frequency: PCLK4 frequency = 1: 8, 1: 4, 1: 2, 1: 1, 2: 1, 4: 1, 8: 1

### 5.3.3 Crystal Oscillator Circuit

#### 5.3.3.1 External High-speed Oscillator

##### 5.3.3.1.1 Oscillator Mode

External high-speed oscillator provides a more accurate timer for the system clock.

XTAL is turned on and off through the CMU\_XTALCR.XTALSTP bit.

The CMU\_OSCSTBSR.XTALSTBF bit indicates whether the external high-speed oscillator is stable or not. The stability time is configured through register CMU\_XTALSTBCR. CMU\_XTALSTBCR must be set at a stable time greater than or equal to that required by the crystal oscillator manufacturer.

The circuit constant of the crystal oscillator varies with the parasitic capacitance of the crystal oscillator and the installed circuit, so it must be discussed carefully with the crystal oscillator manufacturer.

Oscillator features are closely associated with the user's circuit board design, and crystal oscillator and load capacitance must be as close to the oscillator pin as possible to minimize output distortion and vibration stabilization time. The load capacitance value must be adjusted appropriately depending on the oscillator selected. It is not possible to pass the signal line near the oscillating circuit, otherwise it may not be able to oscillate normally due to inductance.

Figure 5-3 External High Speed Oscillator Connection Example

#### 5.3.3.1.2 Clock Input Mode

An external clock source must be provided in clock input mode. This mode is selected by setting the CMU\_XTALCFGR.XTALMS to 1 and the CMU\_XTALCR.XTALSTP to 0. An external clock signal with a duty period of approximately 50% must be used to drive the XTAL\_OUT/XTAL\_EXT pins. At this time, the XTAL\_IN pin can be configured as GPIO according to register settings.

Figure 5-4 External Clock Input Connection Example

#### 5.3.3.2 External High-speed Oscillator Fault Detection

Oscillator fault detection is used to detect whether the oscillation of the external high-speed oscillator (XTAL) is normal.

Open or close by register CMU\_XTALSTDCR.XTALSTDE bit.

After reset release, the external high-speed oscillator stops oscillating, and the external high-speed oscillator fault detection function is disabled. To enable the external high-speed oscillator fault detection function, the external high-speed oscillator must be oscillating, and after waiting for the external high-speed oscillator to stabilize (CMU\_OSCSTBSR.XTALSTBF is 1), it can be turned on through the CMU\_XTALSTDCR.XTALSTDE register.

PLLH and PLLA select XTAL clock as the input source, they can only select the XTAL oscillation fault to generate reset function.

Since oscillator fault detection detects abnormal oscillation of the oscillator caused by external factors, the oscillator oscillation fault detection function should be disabled when stopping the external high-speed oscillator through software or transitioning to Stop mode and and Power-down mode.

If the external high-speed oscillator fails, the action waveform is shown in the following figure. For the operation procedure, please refer to "[XTAL Fault Detection Action Detected](#)".

Figure 5-5 External High-speed Oscillator Fault Detection Example

#### 5.3.3.2.1 Action upon Detection of XTAL Fault

When an external high-speed oscillator oscillation fault is detected, if the system clock selects the external high-speed oscillator as the system clock, the system clock will automatically switch to MRC.

When an external high-speed oscillator oscillation fault is detected, it can trigger EMB to set the PWM output of Timer6/Timer4 to Hi-Z output. For more information, please refer to the relevant description in the "Emergency Brake Module (EMB) " chapter.

When the system clock is selected as XTAL and an XTAL oscillation fault is detected, the action example is as follows:

Figure 5-6 System Clock Selected as XTAL, Example of Detecting XTAL Oscillation Fault

### 5.3.3.2.2 Interrupt Reset Generated upon Detection of XTAL Oscillation Fault

The XTAL oscillation fault interrupt can be configured as a maskable interrupt or a non-maskable interrupt. For more information, please refer to the "Interrupt Controller (INTC) " chapter.

When the XTAL oscillation fault is configured as a reset, if an XTAL oscillation fault is detected, the chip will generate a reset. Please refer to the "Reset Module Unit (RMU) " chapter for reset actions.

### 5.3.3.3 External High-speed Oscillator Fractional Division

By setting the CMU\_XTALDIVR register, the external high-speed oscillator clock can be divided down to 32.768kHz for use by the RTC.

Example setting for dividing the external high-speed oscillator from 10MHz to 32.768kHz:

$$\text{Division number} = \frac{10000000\text{Hz}}{32768\text{Hz}} = \frac{78125(\text{Decimal})}{256(\text{Decimal})} = \frac{0x1312D(\text{Hexadecimal})}{0x100(\text{Hexadecimal})}$$

Set the NUMER[16:0] register to 0x1312D and the DENOM[10:0] register to 0x100. In other words, set the CMU\_XTALDIVR register to 0x1312D100, and then initiate the process via the CMU\_XTALDIVCR register.

Example setting for dividing the external high-speed oscillator from 8MHz to 32.768kHz:

$$\text{Division number} = \frac{8000000\text{Hz}}{32768\text{Hz}} = \frac{31250(\text{Decimal})}{128(\text{Decimal})} = \frac{0x7A12(\text{Hexadecimal})}{0x80(\text{Hexadecimal})}$$

Set the NUMER[16:0] register to 0x07A12 and the DENOM[10:0] register to 0x080. In other words, set the CMU\_XTALDIVR register to 0x07A12080, and then initiate the process via the CMU\_XTALDIVCR register.

### 5.3.3.4 External Low-speed Oscillator

The 32.768kHz external low-speed oscillator can provide a more precise clock source for the system clock and real time clock (RTC) circuit. It has the advantages of low power consumption and high precision.

XTAL32 is turned on and off by the CMU\_XTAL32CR.XTAL32STP bit.

The circuit constant of the crystal oscillator varies with the parasitic capacitance of the crystal oscillator and the installed circuit, so it must be discussed carefully with the crystal oscillator manufacturer. Oscillator features are closely associated with the user's circuit board design, and crystal oscillator and load capacitance must be as close to the oscillator pin as possible to minimize output distortion and vibration stabilization time. The load capacitance value must be properly adjusted according to the selected drive capability. It is not possible to pass the signal line near the oscillating circuit, otherwise it may not be able to oscillate normally due to inductance.

Figure 5-7 External Low-speed Oscillator Connection Example

The initialization procedure for XTAL32 upon initial power-on is as follows:

1. Write 1 to the CMU\_XTAL32CR.XTAL32STP bit to stop XTAL32;
2. Set the matching XTAL32 drive capability through CMU\_XTAL32FGR;
3. Set the filter function through CMU\_XTAL32NFR;
4. Write 0 to the CMU\_XTAL32CR.XTAL32STP bit to oscillate XTAL32;
5. Software waits for XTAL32 to stabilize. The stabilization time can be found in the "Electrical Specifications" chapter in the Datasheet.

If the external low-speed oscillator is not used, set the CMU\_XTAL32CR.XTAL32STP bit to 1 to turn off the external low-speed oscillator.

## 5.3.4 Internal RC Clock

### 5.3.4.1 HRC Clock

The HRC clock signal is generated by an internal high-speed oscillator and can be used directly as a system clock, or as an PLLH, PLLA input. The frequency of HRC can be configured to 16MHz or 20MHz by ICG1.HRCFREQSEL.

The advantage of the HRC oscillator is its low cost (no external components are required). In addition, its startup speed is faster than that of the XTAL crystal oscillator. However, even after calibration, its accuracy is not as good as that of an external crystal oscillator.

### Frequency Calibration

Due to differences in production processes, the RC oscillator frequency of different chips varies. Therefore, each device is factory-calibrated to ensure accuracy. Please refer to the "Electrical Specifications-Operating Conditions-Internal Clock Source Characteristics-HRC" chapter of the Datasheet.

If the application is affected by temperature changes, this may also affect the speed of the RC oscillator. Users can fine-tune the HRC frequency through registers.

CMU\_OSCSTBSR.HRCSTBF indicates whether HRC is stable. At startup, hardware sets this bit to 1 before HRC can be used.

HRC can be turned on or off through CMU\_HRCCR.HRCSTP bit.

#### 5.3.4.2 MRC Clock

The MRC clock signal is generated by an internal 8MHz medium-speed oscillator and can be directly used as the system clock.

The advantage of the MRC oscillator is its fast startup speed.

### Frequency Calibration

Due to differences in production processes, the RC oscillator frequency of different chips varies. Therefore, each device is factory-calibrated to ensure accuracy. Please refer to the "Electrical Specifications-Operating Conditions-Internal Clock Source Characteristics-MRC" chapter in the Datasheet.

If the application is affected by temperature changes, this may also affect the speed of the RC oscillator. Users can fine-tune the MRC frequency through registers.

MRC can be turned on or off through the CMU\_MRCCR.MRCSTP bit.

The MRC clock can also be used as a backup clock source in case of XTAL crystal oscillator failure. Please refer to "[Action upon Detection of XTAL Fault](#)".

#### Notice

Disable stopping the MRC clock when using the TRNG module.

#### 5.3.4.3 LRC Clock

The LRC clock signal is generated by the 32.768kHz internal low-speed oscillator and can be used directly as the system clock. LRC can be used as a low-power clock source to keep running in Power-down mode and Stop mode for Timer0, Timer2 and KEYSKAN.

The LRC oscillator features a fast start-up speed.

### Frequency Calibration

Due to differences in production processes, the RC oscillator frequency of different chips varies. Therefore, each device is factory-calibrated to ensure accuracy. Please refer to the "Electrical Specifications-Operating Conditions-Internal Clock Source Characteristics-LRC" chapter in the Datasheet.

If the application is affected by voltage or temperature changes, this may also affect the speed of the RC oscillator. Users can fine-tune the LRC frequency through registers.

LRC can be turned on or off through the CMU\_LRCCR.LRCSTP bit.

#### 5.3.4.4 SWDTLRC Clock

The SWDTLRC clock signal is generated by the internal 10kHz low-speed oscillator dedicated to SWDT. If SWDT is already started through ICG settings, the dedicated internal low-speed oscillator for SWDT will be forcibly turned on and cannot be disabled.

Due to differences in production processes, the RC oscillator frequency of different chips varies. Therefore, each device is factory-calibrated to ensure accuracy. Please refer to the "Electrical Specifications-Operating Conditions-Internal Clock Source Characteristics-SWDTLRC" chapter in the Datasheet.

#### 5.3.4.5 RTCLRC Clock

The RTCLRC clock signal is generated by the internal 32.768kHz low-speed oscillator. RTCLRC can be used as a low-power clock source to keep running in Power-down mode and Stop mode for RTC and WKTM.

The startup speed of the RTCLRC oscillator is fast.

#### Frequency Calibration

Due to differences in production processes, the oscillator frequency of different chips varies. Therefore, each device is factory-calibrated to ensure accuracy. Please refer to the "Electrical Specifications-Operating Conditions-Internal Clock Source Characteristics-RTCLRC" chapter in the Datasheet.

If the application is affected by voltage or temperature changes, this may also affect the speed of the RC oscillator. Users can fine-tune the RTCLRC frequency through registers.

RTCLRC can be turned on or off through the LRCEN bit in the RTC\_CR3 control register.

#### 5.3.5 PLL Clock

This product is equipped with two PLLs (PLLH and PLLA) :

- Both PLLH and PLLA can select XTAL or HRC oscillator as the input clock, configured uniformly by the CMU\_PLLHCFGR.PLLSRC bit;
- PLLH has three output clocks: PLLHP, PLLHQ, PLLHR, with independently configurable division factors;
- PLLA has three output clocks: PLLAP, PLLAQ, PLLAR, with independently configurable division factors;
- The PLLHP clock can be used as the system clock;
- The PLLHQ, PLLHR, PLLAP, PLLAQ, PLLAR clocks can be used to generate USB, ADC, DAC, I2S, CAN, MCAN clocks.

#### Notice

1. Configure the PLL after the HRC or XTAL oscillator is stable.
2. Since PLL configuration parameters cannot be changed after the PLL is enabled, it is recommended to configure the PLL first and then enable it.
3. When entering Power-down mode and Stop mode, the PLL will be disabled by hardware.

#### 5.3.6 Clock Switching Steps

After system reset, the default system clock is MRC. Switch the clock source by setting the CMU\_CKSW register. Please refer to "[Clock Source Switch](#)" for switching steps. Clock sources can only be switched from one to another when the target clock source is stable.

The waiting period of Flash/SRAM should be configured correctly to prevent the system clock frequency from being larger than the maximum operating frequency of Flash/SRAM. For detailed configuration,

please refer to the "CPU Clock and Flash Read Time Relationship" section of the "Embedded Flash Memory (EFM) " and the "Built-in SRAM (SRAM) " chapter.

### Clock Source Switching

Figure 5-8 Clock Source Switching Flowchart

## Clock Division Switching

Figure 5-9 Clock Division Switching Flowchart

### 5.3.7 Clock Output Function

There are two clock outputs:

- MCO\_1

Users can output different clock sources to the MCO\_1 pin through a configurable pre-divider (1, 2, 4, 8,..., 128 division) :

- ▶ HRC Clock
- ▶ MRC Clock
- ▶ LRC Clock
- ▶ XTAL Clock
- ▶ XTAL32 Clock
- ▶ PLLHP/PLLHQ Clock

- ▶ PLLAP/PLLAQ/PLLAR Clock
- ▶ System Clock

The desired clock source is selected by the CMU\_MCO1CFGR.MCO1SEL bit.

#### ● MCO\_2

Users can output different clock sources to the MCO\_2 pin through a configurable pre-divider (1, 2, 4, 8,..., 128 division) :

- ▶ HRC Clock
- ▶ MRC Clock
- ▶ LRC Clock
- ▶ XTAL Clock
- ▶ XTAL32 Clock
- ▶ PLLHP/PLLHQ Clock
- ▶ PLLAP/PLLAQ/PLLAR Clock
- ▶ System Clock

The desired clock source is selected by the CMU\_MCO2CFGR.MCO2SEL bit.

The output clock of MCO\_1/MCO\_2 should not exceed 100MHz (maximum I/O speed).

### 5.3.8 Clock Frequency Measurement

#### 5.3.8.1 Clock Frequency Measurement Function

Figure 5-10 Clock Frequency Measurement Timing Diagram

- Select the reference clock and the clock to be measured, the clock division, and the active edge of the reference clock using FCM\_MCCR/FCM\_RCCR.
- After writing 1 to the FCM\_STR.START bit, the active edge selected by the EDGES bit is detected, and the counter starts counting up.
- When the active edge selected by the next EDGES bit of the reference clock is detected, the value of the counter is saved to the FCM\_CNTR register and compared with the set value of FCM\_LVR/FCM\_UVR. When  $\text{FCM\_LVR} \leq \text{FCM\_CNTR} \leq \text{FCM\_UVR}$ , the clock frequency measurement is normal.

When  $FCM\_LVR > FCM\_CNTR$  or  $FCM\_CNTR > FCM\_UVR$ , the clock frequency is abnormal, and an interrupt or reset can occur based on the `ERRINTRS/ERRRE/ERRIE` settings.

- After the `START` bit of `FCM_STR` is written to 0, the counter counting is stopped and cleared.
- The counter is divided into 4 groups, and each counter is independent of the others.
- When  $FCM\_LVR > FCM\_CNTR$  or  $FCM\_CNTR > FCM\_UVR$ , the clock frequency is abnormal, and the abnormal source is `FCM_FERR`.

#### 5.3.8.2 Digital Filter Function

External pin input reference clock `FCMREF` has digital filtering function. Digital filtering function performs 3 samples based on the sampling clock selected by the `DNFS` bit. If the levels of the 3 samples are the same, this level is sent internally.

The digital filtering function can set the digital filtering function to be active or inactive and the sampling clock.

#### 5.3.8.3 Interrupt/Reset Function

The clock frequency measurement circuit supports three interrupt requests:

- Frequency abnormal interrupt
- Frequency measurement end interrupt
- Counter overflow interrupt

The clock frequency measurement circuit supports one reset request:

- Frequency exceptionally reset

## 5.4 Register Description

### 5.4.1 Register List

FCM Base Address: 0x40048400

Table 5-3 Clock Frequency Measurement (FCM) Register Offset

| Offset          | Register  | Description                                  | Width |
|-----------------|-----------|----------------------------------------------|-------|
| 0x00+0x40*(n-1) | FCMn_LVR  | FCM Lower Limit Control Register (n=1-4)     | 32    |
| 0x04+0x40*(n-1) | FCMn_UVR  | FCM Upper Limit Control Register (n=1-4)     | 32    |
| 0x08+0x40*(n-1) | FCMn_CNTR | FCM Counter Register (n=1-4)                 | 32    |
| 0x0C            | FCM_STR   | FCM Start Control Register                   | 32    |
| 0x10+0x40*(n-1) | FCMn_MCCR | FCM Measurement Control Register (n=1-4)     | 32    |
| 0x14+0x40*(n-1) | FCMn_RCCR | FCM Reference Control Register (n=1-4)       | 32    |
| 0x18+0x40*(n-1) | FCMn_RIER | FCM Reset Interrupt Control Register (n=1-4) | 32    |
| 0x1C            | FCM_SR    | FCM Flag Register                            | 32    |
| 0x20+0x40*(n-1) | FCMn_CLR  | FCM Flag Clear Register (n=1-4)              | 32    |

CMU Base Address: 0x40048000

Table 5-4 Clock Module Unit (CMU) Register Offset

| Offset | Register       | Description                                             | Width |
|--------|----------------|---------------------------------------------------------|-------|
| 0x4400 | CMU_XTAL32CR   | CMU XTAL32 Control Register                             | 8     |
| 0x4404 | CMU_XTAL32CFGR | CMU XTAL32 Config Register                              | 8     |
| 0x4414 | CMU_XTAL32NFR  | CMU XTAL32 Filter Control Register                      | 8     |
| 0x441C | CMU_LRCCR      | CMU LRC Control Register                                | 8     |
| 0x4424 | CMU_LRCTRM     | CMU LRC Trimming Register                               | 8     |
| 0x442C | CMU_RTCLRCTRM  | CMU RTCLRC Trimming Register                            | 8     |
| 0x4C78 | CMU_XTALCFGR   | CMU XTAL Config Register                                | 8     |
| 0x0018 | CMU_XTALDIVR   | CMU XTAL Fractional Frequency Division Config Register  | 32    |
| 0x001C | CMU_XTALDIVCR  | CMU XTAL Fractional Frequency Division Control Register | 32    |
| 0xC0A2 | CMU_XTALSTBCR  | CMU XTAL Stable Control Register                        | 8     |
| 0xC032 | CMU_XTALCR     | CMU XTAL Control Register                               | 8     |
| 0xC040 | CMU_XTALSTDCR  | CMU XTAL Clock Stop Detect Control Register             | 8     |

| Offset | Register       | Description                                | Width |
|--------|----------------|--------------------------------------------|-------|
| 0xC041 | CMU_XTALSTDSR  | CMU XTAL Clock Stop Detect Status Register | 8     |
| 0xC036 | CMU_HRCCR      | CMU HRC Control Register                   | 8     |
| 0xC062 | CMU_HRCTRM     | CMU HRC Trimming Register                  | 8     |
| 0xC038 | CMU_MRCCR      | CMU MRC Control Register                   | 8     |
| 0xC061 | CMU_MRCTRM     | CMU MRC Trimming Register                  | 8     |
| 0xC100 | CMU_PLLHCFGR   | CMU PLLH Config Register                   | 32    |
| 0xC02A | CMU_PLLHCR     | CMU PLLH Control Register                  | 8     |
| 0xC104 | CMU_PLLACFGR   | CMU PLLA Config Register                   | 32    |
| 0xC02E | CMU_PLLACR     | CMU PLLA Control Register                  | 8     |
| 0xC03C | CMU_OSCSTBSR   | CMU Clock Source Stable Status Register    | 8     |
| 0xC026 | CMU_CKSWR      | CMU System Clock Source Switch Register    | 8     |
| 0xC020 | CMU_SCFGR      | CMU Clock Divider Config Register          | 32    |
| 0xC024 | CMU_USBCKCFGR  | CMU USB Clock Config Register              | 8     |
| 0xC018 | CMU_CANCKCFGR  | CMU CAN Clock Config Register              | 16    |
| 0xC010 | CMU_PERICKSEL  | CMU ADC/DAC Clock Config Register          | 16    |
| 0xC03F | CMU_TPIUCKCFGR | CMU Debug Clock Config Register            | 8     |
| 0xC012 | CMU_I2SCKCFGR  | CMU I2S Clock Config Register              | 16    |
| 0xC03D | CMU_MCO1CFGR   | CMU MCO1 Clock Output Config Register      | 8     |
| 0xC03E | CMU_MCO2CFGR   | CMU MCO2 Clock Output Config Register      | 8     |

## 5.4.2 CMU XTAL Config Register (CMU\_XTALCFGR)

| Offset | Bit Position |        |         |          |   |   |   |   |
|--------|--------------|--------|---------|----------|---|---|---|---|
| 0x4C78 | 7            | 6      | 5       | 4        | 3 | 2 | 1 | 0 |
| Reset  | 0x80         |        |         |          |   |   |   |   |

| 0   | XTALSTP  | XTAL Oscillator Start/Stop Control | <ul style="list-style-type: none"> <li>0b0: XTAL oscillator oscillating</li> <li>0b1: XTAL oscillator stopped</li> </ul> | RW     |

#### Notice

1. When XTAL is selected as system clock or PLLH/PLLA clock source, writing 1 to XTALSTP to stop XTAL oscillator is prohibited.
2. Software sets the XTAL oscillator to oscillate, and after confirming that the XTAL oscillator is stable through the XTALSTBF bit, the system can enter stop mode, Power-down mode, or software sets the XTAL oscillator to stop.
3. The XTAL oscillator is set to stop by software, and the XTAL oscillator can be entered into Stop mode, Power-down mode, or restarted after confirming that the XTAL oscillator is stopped through the XTALSTBF bit.

## 5.4.7 CMU XTAL Clock Stop Detect Control Register (CMU\_XTALSTDCR)

| Offset | Bit Position |          |   |   |   |            |           |           |

| 0   | MRCSTP   | MRC oscillator start/stop bit | <ul style="list-style-type: none"> <li>0b0: MRC oscillator oscillating</li> <li>0b1: MRC oscillator stopped</li> </ul> <div>  <b>Note</b> <ul style="list-style-type: none"> <li>When the XTAL oscillation fault function is enabled, this bit is cleared simultaneously, and MRC oscillates.</li> <li>The Stop mode wake-up action when PWC_STPMCR.CKSMRC bit is 1 is set when the MRC oscillator is oscillating.</li> </ul> </div> | RW     |

**Notice**

1. When MRC is selected as the system clock source, stopping the MRC clock by writing 1 to MRCSTP is prohibited.
2. After software sets the MRC oscillator to oscillate, wait for 5 MRC periods before entering Stop mode, Power-down mode, or stopping MRC.
3. The software sets the MRC to stop, and waits for 5 MRC periods before entering the Stop mode, Power-down mode, or restarting the MRC.
4. MRC is used as RTC calibration clock. When RTC is not initialized, there is a possibility of MRC oscillation. When the RTC calibration function is enabled, MRC oscillates regardless of the MRCSTP bit setting.

**Note**

Frequency calibration needs to be within the LRC frequency guarantee range.

## 5.4.17 CMU LRC Control Register (CMU\_LRCCR)

| Offset | Bit Position |   |   |   |   |   |   |        |
|--------|--------------|---|---|---|---|---|---|--------|
| 0x441C | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
| Reset  | 0x00         |   |   |   |   |   |   |        |
| Name   | Reserved     |   |   |   |   |   |   | LRCSTP |
| Access |              |   |   |   |   |   |   | RW     |

| Bit | Name     | Function                      | Description                                                                                                            | Access |
|-----|----------|-------------------------------|------------------------------------------------------------------------------------------------------------------------|--------|
| 7:1 | Reserved | Reserved                      | -                                                                                                                      | -      |
| 0   | LRCSTP   | LRC oscillator start/stop bit | <ul style="list-style-type: none"> <li>0b0: LRC oscillator oscillating</li> <li>0b1: LRC oscillator stopped</li> </ul> | RW     |

**Notice**

- When LRC is selected as the system clock source, stopping the LRC clock by writing 1 to LRCSTP is prohibited.
- After software sets the LRC oscillator to oscillate, wait for 5 LRC periods before entering Stop mode, Power-down mode or stopping LRC.
- The software sets the LRC to stop, and waits for 5 LRC periods before entering the Stop mode, Power-down mode or starting the LRC again.
- When waiting for the XTAL oscillator, HRC, PLLH, PLLA clocks to stabilize, the LRCSTP bit setting is ignored, and LRC oscillates forcibly.

| 7:1 | Reserved | Reserved     | -                                                                                                                                                                                                                                                                                                            | -      |
| 0   | PLLHOFF  | PLLH Enabled | <ul style="list-style-type: none"> <li>0b0: PLLH action starts</li> <li>0b1: PLLH stops</li> </ul> <div>  <b>Note</b><br/>           Do not set this bit to 1 if the PLLH clock is used as the system clock.         </div> | RW     |

**Notice**

- When PLLH is selected as the system clock source, it is prohibited to stop the PLLH clock by writing 1 to PLLHOFF.
- Software sets PLLH action to start, and after confirming that PLLH is stable through the PLLHSTBF bit, the system can enter Stop mode, Power-down mode, or software-configured stop of PLLH.
- Software sets PLLH to stop, and after confirming that PLLH is stopped through the PLLHSTBF bit, the system can enter Stop mode, Power-down mode, or restart PLLH.
- When PLLH selects the XTAL oscillator as the clock source, set PLLH action to start after confirming that the XTAL oscillator is stable through the XTALSTBF bit. When PLLH selects HRC as the clock source, the PLLH action can be set to start after confirming that HRC is stable through the HRCSTBF bit.

**Notice**

- When PLLA is selected as the clock source for I2S/ADC/DAC/USB/CAN/MCAN, it is prohibited to stop the PLLA clock by writing 1 to PLLAOFF.
- Software sets PLLA action to start, and after confirming that PLLA is stable through the PLLASTBF bit, the system can enter Stop mode, Power-down mode, or software-configured stop of PLLA.
- Software sets PLLA to stop, and after confirming that PLLA is stopped through the PLLASTBF bit, the system can enter Stop mode, Power-down mode, or restart PLLA.
- When PLLA selects the XTAL oscillator as the clock source, set PLLA action to start after confirming that the XTAL oscillator is stable through the XTALSTBF bit. When PLLA selects HRC as the clock source, the PLLA action can be set to start after confirming that HRC is stable through the HRCSTBF bit.

## 6 Power Control (PWC)

### 6.1 Introduction

Power controller is used to control the supply, switching and detection of multiple power domains in multiple run modes and low power modes. The power controller consists of a power consumption control logic (PWCL), a power supply voltage detection unit (PVD), and a battery backup control module (BATBKUP) that automatically switches between VCC and battery power.

The operating voltage (VCC) of the chip is 1.8V to 3.63V. The voltage regulator (LDO) supplies power to the VDD and VDDR domains, and the VDDR voltage regulator (RLDO) supplies power to the VDDR domain in Power-down mode or when VCC is powered off. The chip provides two operating modes: high-speed and ultra-low-speed, and three low-power modes: sleep, stop and power-off through the power consumption control logic (PWCL).

The power voltage detection unit (PVD) provides functions such as power on reset (POR), power down reset (PDR), brown out reset (BOR), programmable voltage detection 1 (PVD1), programmable voltage detection 2 (PVD2), reference voltage measurement path, VBAT voltage detection, and VBAT voltage measurement. Among them, POR, PDR, and BOR control the chip reset action by detecting the VCC voltage. PVD1 detects the VCC voltage and resets or interrupts the chip according to the register settings. PVD2 detects VCC voltage or external input detection voltage, and generates reset or interrupt according to register selection. The reference voltage measurement path is a function for measuring the reference voltage using ADC. VBAT voltage detection is a function that reads the register to obtain the VBAT voltage is higher or lower than the VBAT detection voltage. The VBAT detection voltage can be selected as 1.8V or 2.1V using the register. The VBAT voltage measurement function refers to the function of using ADC to measure the 1/2 voltage division of VBAT to obtain the VBAT voltage value.

The battery backup domain maintains power through VBAT when VCC is powered off, ensuring that the real-time clock module (RTC) and wake-up timer (WKTm) can continue to operate and provide power for RLDO. When the chip enters Power-down mode or VCC loses power, the VDDR area can maintain power through RLDO to keep the data of 4KB Ret SRAM.

The analog blocks are equipped with dedicated supply pins for improved analog performance.

### 6.2 Functional Description

#### 6.2.1 Power Distribution

##### 6.2.1.1 Power Distribution Structure

The chip consists of a VCC domain, a VDD power domain, an AVCC power domain, a battery backup domain, and a VDDR domain.

- The VCC domain is powered by the VCC/VSS pins and consists of power control logic (PWCL), power voltage detection unit (PVD), IO level holding circuit, voltage regulator (LDO), external high-speed oscillator (XTAL), internal low-speed oscillator (LRC) and other circuits.
- The VDD power domain is composed of digital logic such as CPU, digital peripherals, RAM, FLASH, etc., and is powered by VDD generated by LDO. The RAM in the VDD domain is divided into 5 groups, consisting of 11 independent modules, and the power-off of each module can be independently controlled by registers.

- The AVCC power domain is the analog power domain, which is mainly composed of analog-to-digital converter (ADC), digital-to-analog converter (DAC), comparator (CMP), programmable gain amplifier (PGA), and input and output pins of the analog system, and is powered by the AVCC/AVSS pin. In order to provide high-precision analog performance, the analog area is equipped with an independent power supply. To ensure higher accuracy of the ADC, the reference voltage of the ADC uses dedicated pins (VREFH, VREFL).
- The BATBKUP power domain is a battery backup domain. The power supply in this area is automatically selected by the power switch to be supplied by VCC or VBAT. When VCC is powered off, the power supply of the backup domain automatically switches to VBAT. The battery backup domain consists of the real-time clock (RTC), the wake-up timer (WKTm), the external low-speed oscillator (XTAL32), and the internal low-speed oscillator for RTC (RTCLRC).
- The VDDR domain consists of 4KB Ret SRAM. Ret SRAM is powered by RLDO. In Power-down mode, Ret SRAM can retain data. When Ret SRAM is not needed, PWC\_VBATCR.VBTRSD can be set to put the chip into Power-down mode or cut off the VDDR domain power supply when VCC is powered off to further reduce power consumption.

The figure below is the power distribution diagram of the chip.

Figure 6-1 Power Supply Configuration Diagram

### 6.2.1.2 Battery Backup Power Domain

The battery backup domain uses an internal power switch to select VCC power supply or VBAT (battery) power supply. The backup domain includes RTC (real-time clock), XTAL32 (external low-speed oscillator), 128-byte backup registers, 4K-byte Ret SRAM, internal low-speed oscillator, and 2 pins RTCIC0-1. When the voltage of the VCC pin decreases, the real-time clock (RTC) and the internal low-speed oscillator of the RTC are powered by the dedicated battery backup power pin (VBAT pin). For applications without an

external battery, it is recommended to connect the VBAT pin to the VCC pin through an external 100nF ceramic decoupling capacitor.

The switching operation of the battery backup function is shown in the following figure. When the VCC voltage drops below  $V_{PDR}$ , the power backup domain switches to be powered by VBAT; when the VCC voltage rises above  $V_{POR}$ , the power backup domain switches to be powered by VCC. If the chip uses Power-down mode 3 or Power-down mode 4, the detection level of  $V_{PDR}$  cannot be determined. When the VCC voltage drops, it cannot be guaranteed that the chip can correctly switch to the VBAT power supply. Therefore, the chip cannot use Power-down mode 3 and battery backup function at the same time, nor can it use Power-down mode 4 and battery backup function at the same time.

Figure 6-2 Battery Backup Domain Power Switching Diagram

The clock source of the RTC can be the internal low-speed oscillator (RTCLRC) for the RTC or an external low-speed oscillator (XTAL32). Before entering power saving mode through WFI/WFE instructions, Cortex-M4 needs to set the expected wake-up time through the RTC register and enable the wake-up function to implement the RTC timer wake-up event.

Ret SRAM can still retain data in Power-down mode or even after VCC power is lost, so if VBAT is continuously powered, Ret SRAM can be regarded as an internal EEPROM. When an intrusion event occurs, the software setting can be used to select whether the Ret SRAM should be powered off and whether the backup register needs to be initialized. Ret SRAM can be turned off by setting the VBTRSD bit in register PWC\_VBATCR. After the Ret SRAM is turned off, circuits such as a voltage regulator that supplies power to the Ret SRAM are also turned off, which can further reduce power consumption. After the VBTRSD bit is set, the SRAM cannot perform read and write operations until the RAMVALID flag bit becomes 1.

When using the battery backup domain, you need to write the PWC\_VBATRSTR register to initialize the VBAT domain. After PWC\_VBATRSTR writes 0xA5, the external low-speed oscillator XTAL32, the RLDO for Ret SRAM is started, and the wake-up timer WKTM is initialized.

### 6.2.2 Power Voltage Detection Unit (PVD) description

The power voltage detection unit (PVD) includes power on reset (POR), power down reset (PDR), brown out reset (BOR), programmable voltage detection 1 (PVD1), programmable voltage detection 2 (PVD2), reference voltage measurement path, VBAT voltage detection, VBAT voltage measurement and other functions.

### 6.2.2.1 Power-on/Power-off Reset Action Description

The chip is integrated with power-on reset circuit and power-off reset circuit. The power-on reset and power-off reset waveforms are as shown. When  $V_{CC}$  is higher than the specified threshold  $V_{POR}$ , after the  $T_{RSTPOR}$  time, the chip releases the power-on reset state, and the CPU starts to execute code. When  $V_{CC}$  is lower than  $V_{PDR}$ , the chip remains in reset state. When power-on reset is used, the reset pin NRST must be 1. If the reset pin is pulled down, the chip will be reset and started by pin reset.

For detailed information on parameters such as  $V_{POR}$ ,  $V_{PDR}$ , and  $T_{RSTPOR}$ , refer to the "Electrical Characteristics" chapter of the Datasheet.

Figure 6-3 Power-on Reset, Power-off Reset Waveforms

### 6.2.2.2 Brown-out Reset (BOR) Description

During power-up, until  $V_{CC}$  is higher than  $V_{BOR}$ , a brown-out reset (BOR) will put the chip in reset.

The  $V_{BOR}$  threshold is configured through the BOR\_LEV, BORDIS of the initialization configuration bits (ICG). When BORDIS=0b0, the BOR detection voltage can be selected from 4 thresholds. When BORDIS is configured as 0b1, the chip performs reset control through power-on reset and power-off reset.

Table 6-1 BOR Configuration

| BORDIS | BOR_LEV | Description                                |
|--------|---------|--------------------------------------------|
| 0b1    | 0bXX    | BOR Inactive                               |
| 0b0    | 0b00    | BOR Active, Select BOR Threshold 0 (VBOR0) |
| 0b0    | 0b01    | BOR Active, Select BOR Threshold 1 (VBOR1) |
| 0b0    | 0b10    | BOR Active, Select BOR Threshold 2 (VBOR2) |
| 0b0    | 0b11    | BOR Active, Select BOR Threshold 3 (VBOR3) |

For the electrical characteristics of the BOR threshold, see the "Electrical Characteristics" chapter of the Datasheet.

Figure 6-4 Brown-out Reset Waveform

### 6.2.2.3 Programmable Voltage Detection 1 (PVD1), Programmable Voltage Detection 2 (PVD2)

Programmable voltage detection 1 and programmable voltage detection 2 trigger corresponding reset or interrupt actions by detecting whether the VCC power supply voltage passes the detection threshold. Each detection circuit can be programmed and configured separately.

When the power supply voltage passes through the threshold voltage point of each detection circuit, the event can be programmed and configured as a reset/interrupt (maskable/non-maskable) /AOS trigger function.

The main features of programmable voltage detection are shown in the following table.

Table 6-2 PVD1/PVD2 Features

| Item                    | PVD1                                                                                                                                                                          | PVD2                                                                                                                                                                                                                                     |

#### 6.2.2.5 Input/Output Pin

| Pin Name  | Input/Output | Function                               |
|-----------|--------------|----------------------------------------|
| PVD2EXINP | Input        | External input PVD2 comparison voltage |

#### 6.2.2.6 PVD1 Interrupt and Reset

When using the PVD1 circuit in Stop mode or Power-down mode, please observe the following precautions:

1. Stop Mode
  - The digital filter must be disabled.
2. Power-down Mode
  - The digital filter must be disabled.
  - PVD1IRS is set to 0, and PVD1 is selected to generate an interrupt; when the reset function is selected, Power-down mode cannot be entered.

The figure below is the running timing diagram of the voltage monitoring 1 interrupt. PVD1DETFLG needs to be cleared before the interrupt can occur again.

Figure 6-7 Power Monitor 1 Interrupt Timing Diagram

Figure 6-8 Power Monitor 1 Reset Timing Diagram

### 6.2.2.7 PVD2 Interrupt and Reset

When using the PVD2 circuit in Stop mode or Power-down mode, please observe the following precautions:

1. Stop Mode
  - The digital filter must be disabled.
2. Power-down Mode
  - The digital filter must be disabled.

- PVD2IRS is set to 0, and PVD2 is selected to generate an interrupt; when the reset function is selected, Power-down mode cannot be entered.

The figure below is the running timing diagram of the voltage monitoring 2 interrupt. PVD2DETFLG needs to be cleared before the interrupt can occur again.

Figure 6-9 Power Monitor 2 Interrupt Timing Diagram

Figure 6-10 Power Monitor 2 Reset Timing Diagram

### 6.2.2.8 Internal Voltage Sampling and Detection Function

The internal voltage sampling and detection functions of the chip comprise three key features: reference voltage measurement, VBAT voltage detection, and VBAT voltage measurement. The reference voltage measurement path is a function for measuring the reference voltage using the ADC. The internal refer-

ence voltage is approximately 1.15V. VBAT voltage detection is a function that reads the register to obtain the VBAT voltage is higher or lower than the VBAT detection voltage. The VBAT detection voltage can be selected as 1.8V or 2.1V using the register. The VBAT voltage measurement function refers to the function of using ADC to measure the 1/2 voltage division of VBAT to obtain the VBAT voltage value.

Figure 6-11 Internal Voltage Sampling Diagram

#### ● Reference Voltage Measurement Path

When using the reference voltage measurement path, you need to select the reference voltage measurement path according to the following steps.

1. `PWC_PWRC4.ADBUFS=0b0`, select the internal reference voltage;
2. `PWC_PWRC4.ADBUFE=0b1`, enable internal voltage measurement function;
3. `ADC_EXCHSELR.EXCHSEL=0b1`, enables ADC to select the internal voltage measurement channel;
4. Use ADC to measure internal reference voltage after waiting 50μs.

#### ● VBAT Voltage Detection

When using the VBAT voltage detection path, you need to select the VBAT voltage detection path according to the following steps.

1. `PWC_PWRC4.VBATREFSEL=0b1`, select `VBATREF=2.1V`;  
`PWC_PWRC4.VBATREFSEL=0b0`, select `VBATREF=1.8V`;
2. `PWC_PWRC4.VBATME=0b1`, enable VBAT voltage divider circuit;
3. Wait for 50μs;
4. Read the `PWC_PWRC4.VBATMON` bit. When it reads 0b0, `VBAT>VBATREF`. When read as 0b1, `VBAT<VBATREF`.

#### ● VBAT Voltage Measurement

When using the VBAT voltage measurement path, you need to select the VBAT voltage measurement path according to the following steps.

1. `PWC_VBATCR.VBATDIVMONE=0b1`, enable VBAT voltage divider measurement;
2. `PWC_PWRC4.VBATME=0b1`, enable VBAT voltage divider circuit;
3. `PWC_PWRC4.ADBUFS=0b1`, select 1/2 voltage division of VBAT;
4. `PWC_PWRC4.ADBUFE=0b1`, enable internal voltage measurement function;

5. ADC\_EXCHSELR.EXCHSEL=0b1, enables ADC to select the internal voltage measurement channel;
6. Wait for 50μs and then use ADC to measure the VBAT voltage;
7. PWC\_VBATCR.VBATDIVMONE=0b0, turn off VBAT voltage divider measurement.

### 6.2.3 Wake-up Timer

The chip has a built-in wake-up timer WKTM. The counter can select the RTC internal low-speed oscillator (RTCLRC) and external low-speed oscillator as the clock source. When the RTC uses an external low-speed oscillator as the clock action, the 64Hz internal clock signal can also be selected as the clock source. This counter is an add counter. After PWC\_WKTC2.WKTCE is set, the counter starts counting. When the count value is equal to the WKTCMP[11:0] setting value of PWC\_WKTC1 and PWC\_WKTC0, the counter count is cleared and then counts again, and a match consistency event is generated. This event can be used as a normal interrupt and can be used to wake up the Stop mode and Power-down mode.

The value of the WKTM register is uncertain after power-on reset. After power-on reset, must first set the VBAT area reset register, then set PWC\_WKTC0/PWC\_WKTC1/PWC\_WKTC2. Before starting WKTM, make sure the counting clock is on.

### 6.2.4 Action Mode and Low Power Mode

#### 6.2.4.1 Mode Overview

After the system reset or power-on reset, all the power fields of the chip are in the power supply state, and the chip enters the high-speed run mode. In run mode, the CPU provides the clock through HCLK and executes program code. The chip provides 2 run modes: high-speed run mode and ultra low-speed run mode. The chip can be configured in the following run modes.

Table 6-4 RUN Mode

| RUN Mode                 | Description                  |
|--------------------------|------------------------------|
| High-speed RUN Mode      | Main frequency $\leq$ 240MHz |
| Ultra Low-speed RUN Mode | Main frequency $\leq$ 8MHz   |

In order to save power consumption when the CPU does not need to run, the system provides three low-power modes: Sleep mode, Stop mode, and Power-down mode. The low power consumption modes that the chip can be configured in are shown in the following table. In Sleep mode, the Cortex-M4 core of the chip stops operating, and the peripherals keep running; in Stop mode, the peripherals and CPU of the chip stop operating; in Power-down mode, the power supply of VDD domain is turned off, and the VDD domain peripherals stop operating. The real-time clock and wake-up timer located in the battery backup domain can operate in low-power mode, and the Ret SRAM can retain data.

Table 6-5 Low Power Mode

| Mode       | Description                                            |
|------------|--------------------------------------------------------|
| Sleep Mode | CPU clock stopped, peripherals keep running            |
| Stop Mode  | The chip peripherals and the clocks of CPU are stopped |

| Mode            |       | Description                                                                                                                                                                                                                                                                                     |
|-----------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power-down Mode | PDMD1 | VDD domain power down                                                                                                                                                                                                                                                                           |
|                 | PDMD2 | The voltage detection unit is disabled except the VDD domain power down                                                                                                                                                                                                                         |
|                 | PDMD3 | In addition to the VDD domain being powered down, the power-on reset circuit enters low-power mode, and the voltage detection unit (PVD) is disabled. Compared with Power-down mode 4, when waking up from power down, the chip is completely reset except for PWC_PDWKF0/PWC_PDWKF1/RMU_RSTF0. |
|                 | PDMD4 | In addition to the VDD domain power-off, the power-on reset circuit enters the low power consumption mode, and the voltage detection unit (PVD) is disabled                                                                                                                                     |

Users can choose operating mode and low power mode based on the application to find the best balance between low power consumption, short start-up time, wake-up sources, and system execution efficiency.

Power consumption in operating mode can be optimized by the following methods:

1. Set the most suitable run mode
2. Reduce system clock speed
3. Turn off the clock sources that are not in use
4. Set the PWC\_FCGn (n=0-3) register to turn off unused functions
5. Power off the power of the RAM

The operating conditions of low power mode and the status of each module in low power mode are shown in the table below.

**Table 6-6 Operating Conditions of Low Power Mode and Status of Each Module in Low Power Mode**

| Item                             | Sleep mode                                                             | Stop mode                                                                                            | Power-down Mode                                     |
|----------------------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| Entry                            | PWC_STPMCR.STOP=0b0, PWC_PWRC0.PWDN=0b0, WFI                           | PWC_STPMCR.STOP=0b1, PWC_PWRC0.PWDN=0b0, WFI                                                         | PWC_STPMCR.STOP=0b1, PWC_PWRC0.PWDN=0b1, WFI        |
| Release                          | To interrupt or reset arbitrarily                                      | Interrupt or reset that can be used in Stop mode                                                     | Wake-up event or reset available in Power-down mode |
| External high-speed oscillator   | Optional, can be enabled by software                                   | Stop                                                                                                 | Stop                                                |
| External low-speed oscillator    | Optional, can be enabled by software                                   | Optional, can be enabled by software                                                                 | Optional, can be enabled by software                |
| Internal high-speed oscillator   | Optional, can be enabled by software                                   | Stop                                                                                                 | Power down                                          |
| Internal medium speed oscillator | Optional, can be enabled by software                                   | Stop                                                                                                 | Power down                                          |
| Internal low-speed oscillator    | Optional, can be enabled by software                                   | Optional, can be enabled by software                                                                 | Optional, can be enabled by software                |
| WDT dedicated clock oscillator   | Optional, can be enabled by software                                   | Optional, can be enabled by software                                                                 | Power down                                          |
| PLLA                             | Optional, can be enabled by software                                   | Stop                                                                                                 | Power down                                          |
| PLLH                             | Optional, can be enabled by software                                   | Stop                                                                                                 | Power down                                          |
| CPU                              | Stop (hold)                                                            | Stop (hold)                                                                                          | Power down                                          |

#### 6.2.4.2 RUN Mode

The chip has two operating modes: high-speed and ultra low-speed. According to the speed requirements of the system, set the best operating mode, so that the core voltage and drive capability are adapted to the system clock frequency, so as to achieve the purpose of reducing power consumption. As shown in the following table, according to the PWC\_PWRC2.DVS and DDAS bits, the chip can work in the corresponding run mode. When the chip selection action is in ultra low-speed mode, FLASH and RAM also need to be set to work at low core voltage, so register bits FRMC.LVM=0b1, PWC\_RAMOPM=0x9062 need to be set.

Table 6-7 RUN Mode Description

| RUN Mode                  | Frequency Range | Register Setting |                |                |
|---------------------------|-----------------|------------------|----------------|----------------|
|                           |                 | PWC_PWRC2.DVS    | PWC_PWRC2.DDAS | PWC_PWRC3.DDAS |
| High-speed RUN Mode       | ≤240MHz         | 0b11             | 0b1111         | 0b11111111     |
| Ultra Low-speed RUN Mode* | ≤8MHz           | 0b10             | 0b0000         | 0b00000000     |

#### Note

\*: Ultra low-speed run mode only supports  $T_A = -40^{\circ}\text{C} \sim 85^{\circ}\text{C}$ .

The switching between the high-speed run mode and the ultra low-speed operation mode needs to follow the following process.

- **Switch from high-speed run mode to ultra low-speed run mode**

1. Set the clock source used in ultra low-speed run mode to ensure that the clock source meets the frequency requirements in ultra low-speed run mode;
2. Turn off the clock source and modules that are not required in ultra low-speed run mode to verify that Flash is not programmed or erased;
3. Set FLASH's FRMC.LVM to 0b1 and RAM run mode register PWC\_RAMOPM to 0x9062;
4. Confirm FRMC.LVM=0b1, PWC\_RAMOPM=0x9062;
5. Set PWC\_PWRC2.DDAS to 0b0000, set PWC\_PWRC3.DDAS to 0x00, and PWC\_PWRC2.DVS to 0b10;
6. Wait for TSWMD1 (30μs);
7. The chip operates in ultra low-speed run mode.

- **Switch from ultra low-speed run mode to high-speed run mode**

1. Set PWC\_PWRC2.DDAS to 0b1111, PWC\_PWRC3.DDAS to 0xFF, and PWC\_PWRC2.DVS to 0b11 according to the system frequency requirements;
2. Wait for TSWMD2 (30μs);
3. Set FLASH's FRMC.LVM to 0b0 and RAM run mode register PWC\_RAMOPM to 0x8043;
4. Confirm FRMC.LVM=0b0, PWC\_RAMOPM=0x8043;
5. The chip operates in high-speed run mode.

#### 6.2.4.3 Sleep Mode

In Sleep mode, the CPU stops running and its internal registers remain in the state before entering Sleep mode. The operating status of peripherals and other system modules other than the watchdog and dedicated watchdog does not change.

When set to auto-start through ICG, if the ICG0.WDTSLOFF bit is 0b1, the watchdog stops counting in Sleep mode; if the WDTSLOFF bit is 0b0, the watchdog continues counting in Sleep mode. When the ICG is not set to start automatically, start the watchdog via software startup, if the WDT\_CR.SLOFF bit is 0b1, the watchdog stops counting in Sleep mode; if the WDT\_CR.SLOFF bit is 0b0, the watchdog does not stop counting in Sleep mode.

When set to auto-start through ICG, if the ICG0.SWDTSLPOFF bit is 0b1, the dedicated watchdog stops counting in Sleep mode; if the SWDTSLPOFF bit is 0b0, the dedicated watchdog continues counting in Sleep mode.

- **Enter Sleep Mode**

When PWC\_STPMCR.STOP= 0b0, WFI instructions can be executed to enter Sleep mode.

- **Exit Sleep Mode**

Any interrupt and reset can wake the chip from Sleep mode. When waking up by interrupt, the chip enters interrupt processing program. The chip enters the reset state when exiting Sleep mode through reset.

#### 6.2.4.4 Stop Mode

In Stop mode, the CPU, most peripherals, and timer all stop. The chip maintains CPU internal register and SRAM data, peripheral state and pin state. In the Stop mode, because most of the timer stops working, the voltage regulator also reduces the drive capability, so the chip power consumption will be significantly reduced.

The leakage current in STOP mode is different at different voltage temperatures, and the set drive capability must meet the leakage needs of the chip.

When set to auto-start through ICG, if the ICG0.SWDTSLPOFF bit is 0b1, the dedicated watchdog stops counting in Stop mode; if the SWDTSLPOFF bit is 0b0, the dedicated watchdog continues counting in Stop mode.

Before executing the WFI command into Stop mode, make sure that FLASH is not programmed or erased and that the oscillation stop detect function is disabled, otherwise the chip will enter Sleep mode instead of Stop mode.

Before executing the WFI instruction to enter Stop mode, must ensure that PWC\_PWRC0.PDMDS is configured to 0b00.

In Stop mode, the ADC and DAC also consume power unless disabled before entering Stop mode. To disable DAC, clear DACR.DAE, DACR.DA1E, and DACR.DA2E. To disable ADC, clear the ADC\_STR.STRT bit, set PWC\_FCG3.ADC3, PWC\_FCG3.ADC2, and PWC\_FCG3.ADC1, and then execute the WFI instruction to enter Stop mode.

When waking up from STOP mode, select the clock after waking up and whether to wait for the Flash to stabilize through PWC\_STPMCR.CKSMRC and FLNWT. CKSMRC is used to control the clock source after wakeup. When CKSMRC=0b1, the system clock source of wakeup is MRC. When CKSMRC=0b0, the wake-up system clock remains the same as the clock source before STOP. FLNWT is used to control whether to wait for the Flash to stabilize after waking up. When FLNWT=0b0, it is necessary to wait for the Flash to stabilize when waking up; when FLNWT=0b1, it is not necessary to wait for the Flash to stabilize when waking up. FLNWT must be set when the program is running on RAM, otherwise the chip's action after waking up from STOP is not guaranteed. When the program runs on RAM and enters STOP mode, select CKSMRC=0b1, FLNWT=0b1 to wake up the system in the shortest time.

Before executing the WFI instruction to enter the Stop mode, it is necessary to ensure that the DMA is in the stop state, otherwise the chip may have unguaranteed actions.

Before executing the WFI instruction to enter Stop mode, it is necessary to ensure that the frequency division ratio of HCLK to PCLK1/2/3/4 and EXCLK is controlled at 1:1 or 1:2 or 1:4. If the frequency division ratio of HCLK to any peripheral clock exceeds 1:4, it is necessary to configure PCLK1=PCLK3 and set PCLK1 and PCLK3 as the slowest clocks.

Before executing the WFI command to enter the Stop mode, the digital filter of EIRQ needs to be set to inactive, otherwise the interrupt cannot be used for STOP wake-up.

In the ultra low-speed mode, the chip needs to set PWC\_PWRC1.STPDAS=0b11 before entering the STOP mode; if entering STOP mode when PWC\_PWRC1.STPDAS= 0b00, the chip will consume more current in STOP mode.

When releasing the Stop mode through a non-maskable interrupt, it is necessary to set the corresponding bit of INTC\_NMIER to enable the interrupt; When releasing the stop mode through a maskable interrupt, it is necessary to set the corresponding bit of the INTC\_WKEN register to enable the wake-up permission of the interrupt.

- Enter Stop mode

**Step1.** Clear PWC\_LPMCSR.LPMF;

**Step2.** When PWC\_STPMCR.STOP=0b1 and PWC\_PWRC0.PWDN=0b0, execute WFI instruction to enter stop mode;

**Step3.** Read PWC\_LPMCSR.LPMF. If this bit is 1, the chip has entered STOP mode normally. If this bit is 0, return to step 2.

For the status of the chip's peripherals and clock sources in Stop mode, see the table "[Table 6-6 : Operating Conditions of Low Power Mode and Status of Each Module in Low Power Mode](#)".

- Release Stop mode

The Stop mode can be removed by reset and interrupt. The reset methods that can be used to release Stop mode include pin reset, power-on reset, brown-out reset (BOR), programmable voltage detect 1/2 reset and dedicated watchdog reset. Interrupt events that can be used to release stop mode: pin interrupt EIRQ0-15, voltage detection 1 interrupt, voltage detection 2 interrupt, dedicated watchdog underflow interrupt, real-time clock period interrupt, real-time clock alarm interrupt, wake-up timer interrupt, comparator interrupt, USART1 RX interrupt, Timer0 compare match interrupt, Timer2 compare match interrupt.

When the chip releases the Stop mode through interrupt, it first activates the clock source used before entering the Stop mode. After all clock sources are stabilized, the chip releases the Stop mode. When the WFI instruction is executed to enter the stop mode, an interrupt event that is not used to release the Stop mode is generated. The chip will respond to the interrupt first instead of entering the STOP mode. To prioritize entering STOP mode without executing the interrupt, interrupts that are not used to release the Stop mode must be disabled before executing the WFI instruction.

#### 6.2.4.5 Power-down Mode

In Power-down mode, the power supply of all modules in the VDD domain is cut off, and the power consumption can reach the lowest.

When setting SWDT to start automatically via ICG:

- If ICG0.SWDTSLPOFF is 0b1, the dedicated watchdog will be powered off like other modules in the VDD domain and will no longer count;
- If ICG0.SWDTSLPOFF is 0b0, the chip will enter Stop mode instead of Power-down mode, and the dedicated watchdog oscillator and dedicated watchdog will continue to run.

When SWDT starts by setting the software refresh register:

- If SWDT\_CR.SLPOFF is 0b1, the dedicated watchdog will be cut off from power like other modules in the VDD domain and will no longer count;
- If SWDT\_CR.SLPOFF is 0b0, the chip will enter Stop mode instead of Power-down mode, and the dedicated watchdog oscillator and dedicated watchdog will continue to run.

When the reset of voltage detect 1 and voltage detect 2 is enabled, the chip will enter Stop mode instead of Power-down mode.

Before executing the WFI command to enter the Power-down mode, it is necessary to ensure that the FLASH is not in the programming or erasing state, and the oscillation stop monitoring function is disabled, otherwise the chip will enter the Sleep mode instead of the Power-down mode.

The capacitors used on the VCAP\_1/VCAP\_2 pins of the chip are as follows:

- For chips with both VCAP\_1 and VCAP\_2 pins, each pin can use 0.047μF or 0.1μF capacitance (the total capacity is 0.094μF or 0.2μF).
- For the chip with only VCAP\_1 pin, it can use 0.1μF or 0.22μF capacitance

When the Power-down mode is wakened, it needs to charge VCAP\_1/VCAP\_2 during the process of kernel voltage establishment. On the one hand, the smaller total capacity of VCAP\_1/VCAP\_2 can shorten the charging time and bring rapid response to the application; on the other hand, the larger total capacity of VCAP\_1/VCAP\_2 will prolong the charging time, and provide stronger electromagnetic compatibility

(EMC). Users can choose smaller or larger capacitors according to the requirements of electromagnetic compatibility and system response speed. The total capacity of VCAP\_1/VCAP\_2 of the chip must match the assignment of PWC\_PWRC1.PDTS bit. When the total capacity of VCAP\_1/VCAP\_2 is 0.2μF or 0.22μF, it is necessary to ensure that the PWC\_PWRC1.PDTS bit is cleared before entering Power-down mode. When the total capacity of VCAP\_1/VCAP\_2 is 0.094μF or 0.1μF, ensure that PWC\_PWRC1.PDTS position bit is set before entering the Power-down mode.

By setting PWC\_PWRC0.PDMDS, the power consumption in Power-down mode can be further reduced. The sub-modes of Power-down mode are shown in the following table.

- In Power-down mode 1, the voltage monitoring circuit can be used, and the power-on reset detection circuit is in the active state. Since there is no need to wait for the stability of the VCC domain reference voltage circuit, voltage monitoring circuit, and power-on reset detection circuit when waking up, therefore, while achieving low power consumption, the wake-up time is the shortest.
- In Power-down mode 2, the reference voltage circuit in the VCC domain and the voltage monitoring circuit stop working, and the power-on reset detection circuit is in an active state. When waking up, it needs to wait for the stabilization time of the reference voltage circuit in the VCC domain and the voltage monitoring circuit.
- In Power-down mode 3, the VCC domain reference voltage circuit, voltage monitoring circuit, and power-on reset detection circuit all stop working. It is necessary to wait for these circuits to stabilize when waking up. Therefore, while achieving the lowest power consumption, the wake-up time is longer than Power-down mode 2 and Power-down mode 1.
- Power-down mode 4 has the same circuit that stops working in Power-down mode 3, so Power-down mode 4 has the same power consumption as Power-down mode 3.

For specific power consumption values and wake-up time, please refer to the "Electrical Characteristics" chapter of the "Datasheet".

Table 6-8 Power-down Mode Submodes

| Power-down Mode   | PDMDS | Power Consumption | Wake-up Time | Note                                                                                                                  |
|-------------------|-------|-------------------|--------------|-----------------------------------------------------------------------------------------------------------------------|
| Power-down mode 1 | 0b00  | $I_{PD1}$         | $T_{PD1}$    | VCC domain supply voltage detection unit is enable                                                                    |
| Power-down mode 2 | 0b01  | $I_{PD2}$         | $T_{PD2}$    | The POR and PDR detection circuits in the VCC domain are active, while the BOR, PVD1, and PVD2 functions are inactive |
| Power-down mode 3 | 0b10  | $I_{PD3}$         | $T_{PD3}$    | VCC domain POR, PDR, BOR, PVD1, PVD2 inactive                                                                         |
| Power-down mode 4 | 0b11  | $I_{PD4}$         | $T_{PD4}$    | VCC domain POR, PDR, BOR, PVD1, PVD2 inactive                                                                         |

Relationship between power consumption and wake-up time:  $I_{PD1} > I_{PD2} > I_{PD3} = I_{PD4}$ ,  $T_{PD1} < T_{PD2} < T_{PD3} < T_{PD4}$ .

- Enter Power-down mode
  - Step1.** Clear PWC\_LPMCSR.LPMF;
  - Step2.** When PWC\_STPMCR.STOP=0b1 and PWC\_PWRC0.PWDN=0b1, execute WFI instruction to enter Power-down mode;
  - Step3.** Read PWC\_LPMCSR.LPMF. If this bit is 0, return to step 2; if a power down reset is correctly generated, step 3 will not be executed.

- Release Power-down mode

Power-down mode can be released by Power-down mode wake-up event or reset. The resets that can be used to wake up from Power-down mode include pin reset, power-on reset and voltage detection 0 reset. Events that can wake the system from Power-down mode include: WKUPn\_0/1/2/3 (n=0/1/2/3) wake-up events, real-time clock alarm and timer events, voltage detection 1 wake-up event, voltage detection 2 wake-up event, and wake-up timer event.

After waking up from Power-down mode 1 and Power-down mode 2, reset the chip and execute the program again. The wake-up event can be queried through the Power-down wake-up flag bit, and the reset flag bit can be queried through RSTF0.PDRF.

In Power-down mode 3, POR, PDR, BOR, PVD1, and PVD2 circuits are all in an inactive state. After waking up from Power-down mode 3, all registers except PWC\_PDWKFO/PWC\_PDWKFI/RSTF0 are reset, and the chip work follows a similar power-on reset mode; the reset flag bit can be queried through RMU\_RSTF0.PDRF.

In Power-down mode 4, POR, PDR, BOR, PVD1, and PVD2 circuits are all in an inactive state, and the program is re-executed after the chip is reset; the reset flag bit can be queried through RMU\_RSTF0.PDRF.

The Power-down wake-up event is controlled by the Power-down wake-up enable register (PWC\_PDWKE0-PDWKE3) and the Power-down wake-up event edge selection register (PWC\_PDWKES). When a Power-down wake-up event occurs, the corresponding Power-down wake-up flag (PWC\_PDWKFO-PWC\_PDWKFI) is set. After Power-down wake-up, if the Power-down wake-up flag is not cleared, the chip cannot enter Power-down mode again. The edge of Power-down wake-up event can be selected by PWC\_PDWKES.

When waking up from Power-down mode, the VDD domain will re-supply power, the system executes Power-down wake-up reset, and medium speed oscillator inside the working clock. When waking up from Power-down mode, registers that are not reset see the following table.

| Power-down Mode       | Registers that Are not Reset                                                                                                                                                    |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power-down Mode 1/2/4 | PWC_PWRC0, PWC_PWRC1, PWC_PWRC3, PWC_PDWKE0, PWC_PDWKE1, PWC_PDWKE2, PWC_PDWKES, PWC_PDWKFO, PWC_PDWKFI, PWC_PVDCR0, PWC_PVDCR1, PWC_PVDPCR, PWC_PVDLCR, PWC_PVDICR, PWC_PVDDSR |
| Power-down mode 3     | PWC_PDWKFO, PWC_PDWKFI, RMU_RSTF0                                                                                                                                               |

- Pin status after releasing Power-down mode

In Power-down mode, the chip pins will remain in the state before entering Power-down mode or in high-impedance state according to the register setting value. If PWC\_PWRC0.IORTN=0b10 or 0b11, the pin state is high-impedance in Power-down mode, and the pin is initially high-impedance after the Power-down mode is released. If PWC\_PWRC0.IORTN=0b00, the state of the pin remains in the state before the Power-down mode in the Power-down mode, and the pin is initially in a high-impedance state after waking up. If PWC\_PWRC0.IORTN=0b01, the pins of the chip will remain in the state before entering the Power-down mode, and the state of the pins of the chip will not change even if the registers of the peripherals or pins are set after waking up. After PWC\_PWRC0.IORTN is cleared by software, the pin state is controlled by the peripheral or pin register settings.

- WKTM Power-down mode wake-up event

The chip has a built-in counter WKTM for Power-down wake-up. The counter can select an internal low-speed oscillator or an external low-speed oscillator. When the RTC uses an external low-speed oscillator as the clock action, WKTM can also select a 64Hz internal clock signal as the clock source.

This counter is an accumulative counter. After WKTC0.WKTCE is set, the counter starts counting. When the count value is equal to one period of the value set by WKTCMP[11:0], the counting stops and a wake-up event is generated, waking up the chip from Power-down mode. When using WKTM again, you need to reset WKTC0.WKTCE and set it again.

- PTWK Power-down mode wake-up event

The chip has four PTWK events for waking up from Power-down mode: PTWK0, PTWK1, PTWK2, and PTWK3. By setting PWC\_PDWKE0/PWC\_PDWKE1 through software, one of the four pins WKUPn\_0, WKUPn\_1, WKUPn\_2, and WKUPn\_3 can be enabled to trigger a PTWK event. Each PTWK event can select the rising or falling trigger edge of the trigger pin and has an independent flag bit.

The PTWK power-off wake-up event configuration process is as follows:

1. Configure the corresponding bit of PWC\_PDWKES to select the edge;
2. Configure PWC\_PDWKE0 and PWC\_PDWKE1 to enable the corresponding pins;
3. Clear the corresponding flag in PWC\_PDWKF0.

The structural diagram of configuring PTWK<sub>n</sub> is shown in the figure below.

Figure 6-12 PTWK<sub>n</sub> Structure Diagram

- Battery backup domain operation in Power-down mode

After the chip enters Power-down mode, the battery backup domain Ret SRAM continues to be powered by RLDO, and the RTC/WKTM/backup register continues to be powered by VCC, allowing the RTC/WKTM/Ret SRAM to continue operating or retaining data. The LDO powers the VDDR domain after Power-down wake-up. Before entering Power-down mode, the VBAT voltage measurement function must be disabled.

- Methods of reducing power consumption

Power consumption in operating mode can be optimized by the following methods.

1. Set the most suitable run mode;
2. Reduce system clock speed;
3. Turn off the clock sources that are not in use;
4. Set the PWC\_FCG<sub>n</sub> (n=0/1/2/3) register to turn off unused functions;
5. Power off the power of the RAM.

## 6.2.5 Methods to Reduce Power Consumption

### 6.2.5.1 Reduce System Clock Speed

In run mode, the speed of system clock (HCLK), external bus clock (EXCLK) and peripheral clock PCLK0/PCLK1/PCLK2/PCLK3/PCLK4 can be reduced by programming the prescaler register. These pre-dividers can also be used to reduce the speed of peripherals before entering Sleep mode. For more information, see "Clock Module Unit (CMU)".

### 6.2.5.2 Unused Clock Sources Disabled

The system clock of the chip has the following clock sources:

- External high-speed oscillator (XTAL)
- External low-speed oscillator (XTAL32)
- PLLH clock (PLLH)
- Internal high-speed oscillator (HRC)
- Internal medium speed oscillator (MRC)
- Internal low-speed oscillator (LRC)

SWDT has an independent dedicated internal low-speed oscillator (SWDTLRC); RTC can select an external low-speed oscillator or RTC internal low-speed oscillator (RTCLRC) as the clock source.

Both HRC and PLL are equipped with independent power supply circuits. After HRC is turned off, the power supply of HRC can be turned off by setting the PWC\_PWRC1.VHRCSD bit to further reduce power consumption. After PLLA and PLLH are disabled, the power supply of PLLA and PLLH can be turned off by setting PWC\_PWRC1.VPLLSD=0b11.

For more information, see Clock Module Unit (CMU).

### 6.2.5.3 Functional Clock Stop

The peripheral module of the chip is provided with a clock stop function. By setting the register corresponding position bit, the module which does not need to be used can be stopped, and the clock of the corresponding module is also stopped to reduce the power consumption. In the module stop state, the register inside the module remains in the state it was in before stopping.

### 6.2.5.4 Unused RAM Disabled

Each RAM module in the chip is configured with a function clock stop bit and a Power-down control bit. By setting the module stop bit, it stops providing clocks to RAMs that are not need to be used, thereby reducing power consumption. By setting the Power-down control bit of the module, the corresponding RAM module can be powered down, thereby reducing power consumption. The following table shows the correspondence between RAM modules and Power-down control bits. The corresponding RAM can be powered off by setting the PWC\_RAMPC0.RAMPDCn bit, PWC\_VBATCR.VBTRSD bit.

Table 6-10 RAM Module and RAM Power-down Control Bit

| RAM Module | Description                                    | Power-down Control Bit |
|------------|------------------------------------------------|------------------------|
| SRAM1      | 0x20000000-0x2000FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC0     |
|            | 0x20010000-0x2001FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC1     |
| SRAM2      | 0x20020000-0x2002FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC2     |
|            | 0x20030000-0x2003FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC3     |
| SRAM3      | 0x20040000-0x2004FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC4     |
|            | 0x20050000-0x20057FFF<br>RAM for address space | PWC_RAMPC0.RAMPDC5     |

| RAM Module    | Description                                    | Power-down Control Bit |
|---------------|------------------------------------------------|------------------------|
| SRAM4         | 0x20058000-0x2005FFFF<br>RAM for address space | PWC_RAMPC0.RAMPDC6     |
| SRAMH         | 0x1FFE0000-0x1FFE7FFF<br>RAM for address space | PWC_RAMPC0.RAMPDC7     |

## 7 Initialization Configuration (ICG)

### 7.1 Introduction

After the chip's reset is released, the hardware circuit reads data from FLASH addresses 0x00000400-0x0000046F and loads it into the Initialization Configuration (ICG) register. Addresses 0x00000408-0x0000040B, 0x00000410-0x0000041F, and 0x00000438-0x0000045F are reserved; please write all 1s to ensure normal chip action. When FLASH boot swap is enabled and OTP is not enabled, this region is located in FLASH block 1, sector 0; Otherwise, this region is in FLASH block 0, sector 0. Users can modify the ICG register by programming or erasing sector 0. Addresses 0x00000420-0x00000437 are the data security protection enable region; for details, please refer to the "Functional Description-FLASH Programming and Erase Operations-Data Security Protection" chapter in "Embedded Flash Memory (EFM)". The register reset value is determined by FLASH data.

### 7.2 Register Description

#### 7.2.1 Register List

Base address: 0x00000400

Table 7-1 Initialization Configuration (ICG) Register Offset

| Offset | Register | Description                              | Width |
|--------|----------|------------------------------------------|-------|
| 0x000  | ICG0     | Initialization Configuration Register 0  | 32    |
| 0x004  | ICG1     | Initialization Configuration Register 1  | 32    |
| 0x00C  | ICG3     | Initialization Configuration Register 3  | 32    |
| 0x060  | ICG8A    | Initialization Configuration Register 8A | 32    |
| 0x064  | ICG8B    | Initialization Configuration Register 8B | 32    |
| 0x068  | ICG8C    | Initialization Configuration Register 8C | 32    |

## 7.2.2 Initialization Configuration Register 0 (ICG0)

| Offset | Bit Position |    |           |    |         |    |    |    |        |    |    |    |         |    |        |    |         |    |          |    |           |    |          |   |   |   |         |   |   |   |          |   |         |  |          |  |

## 8 Embedded Flash Memory (EFM)

### 8.1 Introduction

The Flash interface accesses Flash through the ICODE, DCODE, and MCODE buses. The interface can perform programming, erasing and full erasing operations on Flash. Besides, it can accelerate code execution through command prefetching and caching mechanisms.

### 8.2 Features

- Two independent Flash blocks form a dual bank, enabling BGO (BackGround Operation) functionality
- 134KBytes OTP space
- ICODE Bus 16Bytes prefetching
- Two independent cache areas: ICODE bus cache space 4KBytes (256x128); DCODE bus cache space 1KBytes (64x128)
- Supports boot swap function
- Support data security protection
- Features ECC (Error Checking and Correcting), which can correct one-bit errors in 128-bit data and 9-bit ECC, detect one-bit errors in 20-bit address-related information, and detect two-bit errors in 128-bit data with 9-bit ECC and 20-bit address-related information.

## 8.3 Functional Description

### 8.3.1 Embedded Flash

Flash has the following main features:

- Capacity: Up to 2MBytes, consisting of two 1MByte Flash, with a total of 256 sectors, each 8KBytes. Sectors 0-15 in Block 0 can be configured as OTP areas.
- The OTP (One Time Program) area is 134KBytes in total, of which 128KBytes are configured at block 0 address 0x00000000-0x0001FFFF, 6KBytes are configured at address 0x03000000-0x030017FF. Addresses 0x03001800-0x03001F6F are for OTP block latches, 0x03001F70-0x03001FEF are reserved for OTP, and 0x03001FF0-0x03001FFF are for OTP enable addresses.
- 128-bit wide data read: 128-bit wide read cache buffer accelerates code execution.
- The programming unit is 16Bytes. Erase unit: 8KBytes.

**Figure 8-1 Flash Address Distribution**

The OTP area, boot swap enable address, and data security configuration area each have a dedicated sector for programming, erasing, but full erase is disabled. These three sectors physically belong to Flash block 0, and their erase/write flags follow Flash block 0, but their data remains unchanged during a full erase of Flash block 0.

The OTP region spans from 0x03000000 to 0x03001FFF, the boot swap enable function is configured at addresses 0x03002000 to 0x0300200F, and the data security configuration area is located from 0x03004000 to 0x0300400F.

## 8.3.2 Read Interface

### 8.3.2.1 CPU Clock and Flash Read Time Relationship

To correctly read Flash data, users need to set the wait period count (EFM\_FRMC.FLWT) based on the CPU operation frequency.

After system reset, the CPU clock source is MRC (8MHz), and the Flash read wait period is 0. Users are recommended to follow these steps to modify the CPU frequency and Flash read wait period bits: The number of waiting periods is shown in the table below.

**Table 8-1 Compare Table of CPU Clock Frequency (HCLK) and Flash Read Waiting Cycles**

| CPU Clock Frequency (HCLK) | Read Waiting Cycle Setting |
|----------------------------|----------------------------|
| 200MHz<HCLK≤240MHz         | EFM_FRMC.FLWT=0b0101       |
| 160MHz<HCLK≤200MHz         | EFM_FRMC.FLWT=0b0100       |
| 120MHz<HCLK≤160MHz         | EFM_FRMC.FLWT=0b0011       |
| 80MHz<HCLK≤120MHz          | EFM_FRMC.FLWT=0b0010       |
| 40MHz<HCLK≤80MHz           | EFM_FRMC.FLWT=0b0001       |
| HCLK≤40MHz                 | EFM_FRMC.FLWT=0b0000       |

#### CPU Frequency Increase Steps:

- Step1.** Write the new read wait period setting to the EFM\_FRMC.FLWT register.
- Step2.** Read the EFM\_FRMC register to check if the new wait period setting is successful.
- Step3.** Increase the CPU clock frequency by setting the system clock source switch register CMU\_CKSWR.CKSW or the system clock configuration register CMU\_SCFGR.HCLKS.
- Step4.** Read the CMU\_CKSWR or CMU\_SCFGR register to check if the new setting is successful.

#### CPU Frequency Reduction Steps:

- Step1.** Decrease the CPU clock frequency by setting the system clock source switch register CMU\_CKSWR.CKSW or the system clock configuration register CMU\_SCFGR.HCLKS.
- Step2.** Read the register CMU\_CKSWR or CMU\_SCFGR to check if the new setting is successful.
- Step3.** Write the new read wait period setting to the EFM\_FRMC.FLWT register.
- Step4.** Read the EFM\_FRMC register to check if the new wait period setting is successful.

### 8.3.2.2 Normal Read

By default, Flash is in Normal read mode, which is the most commonly used by customers.

### 8.3.2.3 Blank Read

After a Flash sector is erased, all Flash data, including ECC data, is checked to be "1".

Blank read mode setup steps:

1. Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT, then write 0x3210)
  2. Set Blank read mode. (EFM\_FRMC2.BRM0/1=1)
  3. Read the Flash address to be checked.
  4. Check if the read data contains any "0" flags (EFM\_FSR.BRMER0/1).
- If the read data (including ECC data) is not all "1" in the Blank state, EFM\_FSR.BRMER0/1=1.
5. Write 1 to the corresponding flag clear bit in the EFM\_FSCLR register to clear the status bit.

#### 6. Set back to Normal read mode.(EFM\_FRMC2.BRM0/1=0)

The above procedure should be executed on a different Flash block from the check address, or on other memory (e.g., RAM).

### 8.3.3 Flash Read Acceleration Cache

Each Flash read operation is a 128-bit read, with data sent to the CPU and also stored in a buffer register. These 128 bits of data can be 4 rows of 32-bit instructions or 8 rows of 16-bit instructions, depending on the program burned into Flash.

To enable fast reading of Flash data, the Flash controller is configured with a read acceleration cache that optimizes read wait periods. To maximize processor performance, this accelerator stores ICODE and DCODE bus access data in cache memory, improving program execution speed.

The system provides 5KBytes of space as cache memory to actively reduce the time loss caused by instruction jump. Enable the cache function by setting the EFM\_FRMC.ICACHE/DCACHE bit to 1. Whenever an instruction or data miss occurs (i.e., the requested instruction or data is not present in the currently used instruction line or cache memory), the system copies the newly read data line (128 bits) into cache memory. If the instruction or data requested by the CPU is already in the cache, it can be obtained immediately without any delay. When the cache memory is full, the LRU (Least Recently Used) strategy is used to determine which data in the cache memory to replace.

When the CPU reads instructions or data, the Flash address is buffered. When there is a cache hit, the number of Flash read periods changes, as shown in the table below.

Table 8-2 Actual Flash Read Cycle Count

| EFM_FRMC.<br>FLWT Setting | Cache Disable |             | Cache Enable        |                               |
|---------------------------|---------------|-------------|---------------------|-------------------------------|
|                           | Buffer Hit    | Buffer Miss | Buffer or Cache Hit | Miss in Both Buffer and Cache |
| 0                         | 1             | 1           | 1                   | 1                             |
| 1                         | 1             | 2           | 1                   | 2                             |
| 2                         | 1             | 3           | 1                   | 3                             |
| N(N>2)                    | 1             | N+1         | 1                   | N+1                           |

### 8.3.4 Flash Programming and Erasing Operations

#### 8.3.4.1 Overview of Programming and Erase Operations

Flash supports programming, sector erase, and full erase operations.

Flash programming, sector/full erase address must be 4-byte aligned (last bit addresses are: 0x0, 0x4, 0x8, 0xC). The programming unit is 16Bytes. The sector erase unit is 8KBytes. Full erase can be either a single Flash block or two Flash blocks according to register settings. Flash programming methods are divided into three types: single programming without read-back mode, single programming with read-back mode, and continuous programming mode. During Flash programming and erasing, if EFM\_FWMC.BUSHLCTL=0 is set, the bus is occupied until the write/erase is completed; if EFM\_FWMC.BUSHLCTL=1, the bus is released, the bus can continue to access another Flash address. Before Flash programming and erasing, please disable cache enable and prefetch. The following describes the setting steps for programming and erasing operations.

### 8.3.4.2 Unlock EFM\_KEY1 Register

After reset, the Flash programming and erasing mode register (EFM\_FWMC) is in write-prohibited status. It is necessary to first disable the Flash access protection register (EFM\_FAPRT), and then disable the protection of EFM\_KEY1. The following steps are used to disable the above protection:

**Step1.** Remove the Flash register access write protection (EFM\_FAPRT first writes 0x0123, then writes 0x3210)

**Step2.** Unlock EFM\_KEY1 ( write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98 )

If an incorrect sequence is written to EFM\_KEY1, a bus error will occur, and it will self-lock. The EFM\_FWMC register will be write-prohibited until a reset occurs.

After correctly writing the set value to the EFM\_FWMC register, if you need to return to the EFM\_FWMC write-prohibited state, you can write 1 to EFM\_FWMC.KEY1LOCK.

### 8.3.4.3 Write Protection Function

Each Flash sector has 1 write protection bit, located in the write protection register EFM\_F0/1NWPRTx (x=0-3). Each write protection register has 1 write protection lock bit (WLOCK[7:0]). Once the write protection lock bit is set to 1, the write protection register bit can only be set from write-permitted to write-prohibited. When a Flash sector is set to write-prohibited, programming and erasing operations to that sector address will not occur, and an error flag (EFM\_FSR.PRTWERR0/1=1) will be generated.

In full erase mode, if there is one or more sectors in the Flash block set to write-prohibited, full erase will not occur, and an error flag (EFM\_FSR.PRTWERR0/1=1) will be generated.

### 8.3.4.4 Single Programming Without Read-back Function

The steps for single programming without read-back mode are as follows:

**Step1.** Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT first, then write 0x3210)

**Step2.** Unlock the EFM\_KEY1 lock. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)

**Step3.** Set the single programming mode. (EFM\_FWMC.PEMOD=0b001)

**Step4.** Disable write protection. (EFM\_F0/1NWPRTx (x=0-3) corresponding bit is set to 1)

**Step5.** Write 128 of data to the programming address, writing 32-bit data consecutively to programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC (totaling 128 bits).

**Step6.** Wait for the Flash operation to end and for it to be in an idle state. (EFM\_FSR.OPTEND0/1=1, EFM\_FSR.RDY0/1=1)

**Step7.** Read the programming address value and check if it matches the written value:  
If they match, programming is successful. If they do not match, the Flash address has been corrupted and should be permanently discarded.

**Step8.** Clear the end of programming flag. (EFM\_FSR.OPTEND0/1)

Performing a single programming write operation on a locked OTP address without read-back will fail, and the flag bit EFM\_FSR.OTPWERR0 will be set.

If the programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC are not written consecutively, the programming action will not be executed, and the flag bit EFM\_FSR.PGSZERR0/1 will be set.

### 8.3.4.5 Single Programming With Read-back Function

Single programming with read-back mode refers to the hardware automatically reading the programming address data after programming ends and comparing it with the written data to verify correctness by checking the flag bit EFM\_FSR.MISMTCH0/1.

The steps for setting the read mode for single programming are as follows:

- Step1.** Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT, then write 0x3210)
- Step2.** Unlock the EFM\_KEY1 lock. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)
- Step3.** Set single programming with read-back mode. (EFM\_FWMC.PEMOD=0b010)
- Step4.** Disable write protection. (EFM\_F0/1NWPRTx (x=0-3) corresponding bit is set to 1)
- Step5.** Write 128 of data to the programming address, writing 32-bit data consecutively to programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC (totaling 128 bits).
- Step6.** Wait for the Flash operation to end and for it to be in an idle state. (EFM\_FSR.OPTEND0/1=1, EFM\_FSR.RDY0/1=1)
- Step7.** Check the programming self-read result flag bit (EFM\_FSR.MISMTCH0/1) :  
If 0, programming is successful. If 1, the Flash address has been corrupted and should be permanently discarded.
- Step8.** Clear the programming end flag bit (EFM\_FSR.OPTEND0/1).

Performing a single programming read-and-write operation on a locked OTP address will fail, and the flag bit EFM\_FSR.OTPWERR0 will be set.

If the programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC are not written consecutively, the programming action will not be executed, and the flag bit EFM\_FSR.PGSZERR0/1 will be set.

#### 8.3.4.6 Continuous Programming Function

When programming Flash addresses consecutively, it is recommended to use continuous programming mode. Continuous programming mode can save over 50% of the time compared to single programming mode. In continuous programming mode, the interval between Flash address write commands should not exceed 16μs. The steps for setting up continuous programming operations are as follows:

- Step1.** Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT, then write 0x3210)
- Step2.** Unlock the EFM\_KEY1. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)
- Step3.** Set continuous programming mode. (EFM\_FWMC.PEMOD=0b011)
- Step4.** Disable write protection. (EFM\_F0/1NWPRTx (x=0-3) corresponding bit is set to 1)
- Step5.** Write 128 of data to the programming address, writing 32-bit data consecutively to programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC (totaling 128 bits).  
The programming address should be in a different Flash block from the executing program, or the program should run in a region outside of Flash.
- Step6.** Wait for the operation end flag bit (EFM\_FSR.OPTEND0/1) to be set.
- Step7.** Clear the operation end flag bit until EFM\_FSR.OPTEND0/1 reads 0.
- Step8.** Repeat steps 5-7 until all data is written.
- Step9.** Change continuous programming mode to non-continuous programming mode. (EFM\_FWMC.PEMOD=0b000)
- Step10.** Wait for Flash to be in an idle state. (EFM\_FSR.RDY0/1=1)
- Step11.** Read the programming address and check if it matches the written value.  
If they match, programming is successful. If they do not match, the Flash address has been corrupted and should be permanently discarded.

Performing a continuous programming write operation on a locked OTP address will fail, and the flag bit EFM\_FSR.OTPWERR0 will be set.

If the programming addresses with last bit addresses 0x0, 0x4, 0x8, 0xC are not written consecutively, the programming action will not be executed, and the flag bit EFM\_FSR.PGSZERR0/1 will be set.

### 8.3.4.7 Sector Erase Function

After performing a sector erase operation on Flash, the data in the sector (8KBytes of space) is refreshed to all 1s.

The steps for setting the sector erase operation are as follows:

- Step1.** Remove the Flash register write protection (EFM\_FAPRT first writes 0x0123, then writes 0x3210).
- Step2.** Unlock the EFM\_KEY1 lock. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)
- Step3.** Set sector erase mode (EFM\_FWMC.PEMOD=0b100).
- Step4.** Disable write protection. (EFM\_F0/1NWPRTx (x=0-3) corresponding bit is set to 1)
- Step5.** Write any 32-bit value to any address within the sector to be erased (address must be 4-aligned).
- Step6.** Wait for the Flash operation to end and for it to be in an idle state. (EFM\_FSR.OPTEND0/1=1, EFM\_FSR.RDY0/1=1)
- Step7.** Clear the erase end flag bit. (EFM\_FSR.OPTEND0/1)

Performing an erase operation on a locked OTP address will fail, the OTP area data will remain, and the flag bit EFM\_FSR.OTPWERR0 will be set.

### 8.3.4.8 Full Erase Function

EFM provides two erase methods: single block Flash full erase and simultaneous full erase of both blocks.

The steps for setting the full erase operation are as follows:

- Step1.** Remove the Flash register write protection (EFM\_FAPRT first writes 0x0123, then writes 0x3210).
- Step2.** Unlock the EFM\_KEY1 lock. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)
- Step3.** For single block Flash full erase, set EFM\_FWMC.PEMOD=0b101.
- Step4.** For simultaneous full erase of both blocks, set EFM\_FWMC.PEMOD[2:0]=0b110.
- Step5.** Disable write protection. (EFM\_F0/1NWPRTx (x=0-3) Flash block all bits are set to 1)
- Step6.** For single block Flash full erase: Write any 32-bit value to any address within the Flash block to be erased (address must be 4-aligned).
- Step7.** For simultaneous full erase of both blocks, write any 32-bit value to any address within Flash block 0 or block 1 (address must be 4-aligned).  
The full erase action will be automatically synchronized to the other block of Flash.
- Step8.** Wait for the Flash operation to end and for it to be in an idle state. (EFM\_FSR.OPTEND0/1=1, EFM\_FSR.RDY0/1=1)
- Step9.** Clear the erase end flag bit. (EFM\_FSR.OPTEND0/1)

After OTP is enabled, performing a single block full erase write operation on Flash block 0 address will fail, block 0 data will remain, and the flag bit EFM\_FSR.OTPWERR0 will be set; performing a simultaneous full erase write operation on Flash block 0 address will result in block 0 data remaining and block 1 data being erased, and the flag bit EFM\_FSR.OTPWERR0 will be set.

### 8.3.4.9 Data Security Protection

This product provides four protection levels for Flash data to prevent untrusted users from reading and tampering with Flash data through debug interfaces (JTAG and SWD), ISP interfaces (In System Program), and test interfaces.

### Protection Level 0: No Protection

Debug interfaces, ISP interfaces and test interfaces can access (read and rewrite) MCU resources, including Flash data.

### Protection Level 1

After the data 0xAF180402 is programmed into the flash address 0x00000430-0x00000433 and the 96-bit password is programmed into the address 0x03004000-0x0300400B, protection level 1 is enabled.

After enabling protection level 1:

- Debug interfaces, ISP interfaces and test interfaces cannot access MCU resources.
- User programs cannot program or perform sector erases in sector 0.
- The data at addresses 0x03004000-0x0300400B cannot be read.

After activating protection level 1, it can be reset to protection level 0 through password authentication or full erase. If OTP is enabled, full erase is disabled. Please consult the sales window for password authentication and full erase methods.

### Protection Level 2

Protection level 2 is enabled by programming data 0xA85173AE into Flash addresses 0x00000434-0x00000437.

After enabling protection level 2:

- Debug interfaces, ISP interfaces and test interfaces cannot access MCU resources.
- User programs cannot program or perform sector erases in sector 0.

After activating protection level 2, it can be reset to protection level 0 through full erase. If OTP is enabled, full erase is disabled.

### Protection Level 3

Protection level 3 is enabled by programming data 0x42545048 into Flash addresses 0x00000420-0x00000423, 0x00000424-0x00000427, 0x00000428-0x0000042B.

After enabling protection level 3:

- Debug interfaces, ISP interfaces and test interfaces cannot rewrite Flash data.
- User programs cannot program or perform sector erases in sector 0.

After activating protection level 3, it can be reset to protection level 0 through full erase. If OTP is enabled, full erase is disabled.

Protection levels 1, 2, and 3 can be enabled individually or simultaneously. When enabled simultaneously, the protection measures are cumulative.

#### 8.3.4.10 D-BUS Read Protection Function

D-BUS read protection is provided for the address space 0x00000000-0x0001FFFF (128KBytes). To enable D-BUS protection, set the ICG3.DBUSPRT to 0x4450. After a reset, the function is enabled. When the CPU-PC pointer is within this 128KB space (i.e., the CPU is executing a program in this region) : The CPU can access normally. When the CPU-PC pointer is outside this 128KB space (i.e., the CPU is executing a program outside this region) : D-BUS read access to the 128KB space by the CPU is disabled, and a bus error is returned. D-BUS is the CPU's data access bus, including operand access, stack data access, general data access, etc.

### 8.3.4.11 BGO Function

When the target addresses for Flash programming and erasing are not in the same Flash block as the address of the executing program, or when the program is running in RAM, EFM\_FWMC.BUSHLCTL can be set to 1 (bus released during programming and erasing) to allow Flash programming or erasing to occur while the program is executing.

The following are the steps for setting BGO functions:

- Step1.** Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT, then write 0x3210)
- Step2.** Unlock the EFM\_KEY1 lock. (Write 0x01234567 to EFM\_KEY1 first, then write 0xFEDCBA98)
- Step3.** Set the programming, sector erase or full erase mode. (EFM\_FWMC.PE-MOD=0b001/0b010/0b011/0b100/0b101)
- Step4.** Disable write protection. (Set the corresponding sector bits to 1 in EFM\_F0/1NWPRTx (x=0-3) for the target address)
- Step5.** Set the bus release during programming, sector erase or full erase (EFM\_FWMC.BUSHLCTL=1)
- Step6.** 128 bits of data are written to the programming address, and 32 bits of data (a total of 128 bits) are written to the programming addresses whose last addresses are 0x0, 0x4, 0x8, and 0xC respectively.  
(Programming address and executing program should be in different Flash blocks)  
If the executing program is in RAM, both blocks of Flash can be programmed or (full) erased simultaneously.
- Step7.** Wait for the erase/write end flag bit to be set. (EFM\_FSR.OPTEND0/1=1)

### 8.3.5 One-Time Programmable Byte (OTP)

This MCU provides a maximum of 134KBytes of OTP area, and the address distribution is as follows.

Divided into 16x8KBytes, 1x2KBytes, 1x1KBytes, 1x512Bytes, 4x256Bytes, 96x16Bytes.

Table 8-3 OTP Address Distribution Table

| Sector | OTP Block Data Address | Capacity | OTP Block Lock Address |
|--------|------------------------|----------|------------------------|
| 0      | 0x00000000-0x00001FFF  | 8KB      | 0x03001800-0x0300180F  |
| 1      | 0x00002000-0x00003FFF  | 8KB      | 0x03001810-0x0300181F  |
| ...    | ...                    | ...      | ...                    |
| 14     | 0x0001C000-0x0001DFFF  | 8KB      | 0x030018E0-0x030018EF  |
| 15     | 0x0001E000-0x0001FFFF  | 8KB      | 0x030018F0-0x030018FF  |
| 16     | 0x03000000-0x0300000F  | 16B      | 0x03001900-0x0300190F  |
| ...    | ...                    | ...      | ...                    |
| 111    | 0x030005F0-0x030005FF  | 16B      | 0x03001EF0-0x03001EFF  |
| 112    | 0x03000600-0x030007FF  | 512B     | 0x03001F00-0x03001F0F  |
| 113    | 0x03000800-0x03000FFF  | 2KB      | 0x03001F10-0x03001F1F  |
| 114    | 0x03001000-0x030010FF  | 256B     | 0x03001F20-0x03001F2F  |
| 115    | 0x03001100-0x030011FF  | 256B     | 0x03001F30-0x03001F3F  |
| 116    | 0x03001200-0x030012FF  | 256B     | 0x03001F40-0x03001F4F  |
| 117    | 0x03001300-0x030013FF  | 256B     | 0x03001F50-0x03001F5F  |

| Sector | OTP Block Data Address | Capacity | OTP Block Lock Address |
|--------|------------------------|----------|------------------------|
| 118    | 0x03001400-0x030017FF  | 1KB      | 0x03001F60-0x03001F6F  |

To enable OTP functionality, 4x32-bit data containing zeros (recommended to write 128-bit all zeros) need to be programmed into the OTP enable addresses (0x03001FF0-0x03001FFF).

When the OTP block latch addresses contain 4x32-bit data with zeros, the corresponding block space cannot be programmed, erased, or full erased again.

OTP sectors 0-15 share 128KBytes of physical space with Flash block 0 addresses 0x00000000-0x0001FFFF; if the latch address data for this space is all 1s, it is a regular Flash space that can be programmed and erased multiple times; if the latch address data contains zeros, the corresponding sectors are read-only, and Flash block 0 cannot be bulk erased.

To program OTP latch addresses, unlock the EFM\_KEY2 register (EFM\_KEY2 is first written with 0x10325476, then with 0xEFCDAB89). If an incorrect sequence is written to the EFM\_KEY2 register, a bus error will occur, and the EFM\_KEY2 register will lock until reset.

Please follow the steps below to operate the OTP area:

- Step1.** Disable the Flash register write protection. (EFM\_FAPRT: First write 0x0123, then write 0x3210).
- Step2.** Unlock the EFM\_KEY1 lock. (EFM\_KEY1: First write 0x01234567, then write 0xFEDCBA98).
- Step3.** Set programming mode. (EFM\_FWMC.PEMOD=0b001/0b010/0b011).
- Step4.** Write data to OTP addresses as needed.
- Step5.** Unlock the EFM\_KEY2 lock. (EFM\_KEY2: First write 0x10325476, then write 0xEFCDAB89).
- Step6.** Write 0 to any bit of each of the 4x32-bit OTP enable addresses (0x03001FF0-0x03001FFF). (Recommended to write 128-bit all 0)
- Step7.** Write 0 to any bit of each of the 4 32-bit OTP latch addresses. (It is recommended to write 128-bit all 0)

After chip reset, the hardware will automatically load OTP latch address data into the circuit; if the OTP enable addresses (0x03001FF0-0x03001FF) have already been programmed with 0, step 6 can be omitted.

Programming, erasing, or full erasing the OTP data area that has been latched will generate an OTP-WERR0 error flag.

After writing to OTP latch addresses, to return to the EFM\_KEY2 locked state, write 1 to EFM\_FWMC.KEY2LOCK.

### 8.3.6 Boot Swap

Programming data 0x5A5A5A into the boot swap enable address (0x03002000) enables the boot swap function

When OTP functionality is not enabled (0x03001FF0-0x03001FFF are all 1), after programming the boot swap enable address with a reset value, the addresses of Flash block 0 and Flash block 1 are swapped entirely; at this time, the OTP enable addresses cannot be programmed. The boot swap status can be queried through the EFM\_FSWP.FSWP bit.

When OTP functionality is enabled (the 4x32-bit data at 0x03001FF0-0x03001FFF contain zeros), after programming the boot swap enable address with a reset value, the addresses of Flash block 0 and Flash block 1 are partially swapped. At this time, EFM\_FSWP.FSWP is 0, and the address swap function can be judged by reading the data at address 0x03002000.

The swap rules are shown in the figure below:

When the OTP function of 2MBytes product is not enabled, the Flash address distribution

When the OTP function of 2MBytes product is enabled, the Flash address distribution

Figure 8-2 Flash Address Distribution for 2MBytes Products

Taking boot swap with OTP disabled as an example, the usage of this function is introduced.

Figure 8-3 Boot Swap Activation 1

When users need to upgrade the boot program again, since address 0x03002000 has already been programmed, erasing it is required for another upgrade. The operating procedures are as follows:

Figure 8-4 Boot Swap Activation 2

### 8.3.7 Data Reliability and Integrity

Programmed data is stored in Flash with error correction code (ECC) to prevent data loss.

#### 8.3.7.1 ECC in Flash

The 9-bit ECC in Flash is calculated based on 128-bit data and 20-bit address-related information.

The ECC in Flash has the following functions:

- Correcting one-bit errors in 128-bit data and 9-bit ECC.
- Detecting one-bit errors in 20-bit address-related information.
- Detecting two-bit errors in 128-bit data with 9-bit ECC and 20-bit address-related information.

The correction and detection of ECC in Flash are verified and recorded.

By default, ECC is automatically generated during programming. Additionally, by setting EFM\_F0ECCCR/F1ECCCR.GDIS=1, ECC uses the data in EFM\_F0ECCDR/F1ECCDR.DWD during programming.

By default, ECC is verified by hardware during read periods. Additionally, by setting EFM\_F0ECCCR/F1ECCCR.VDIS=1, ECC correction and detection are disabled, and the read ECC is sent to the register EFM\_F0ECCDR/F1ECCDR.DRD.

20-bit Address-Related Information:

- Bit [19]: Reserved bit, fixed to 0.
- Bit [18]: 1 for 0x0300 xxxx space, 0 for block 0 and block 1 space.
- Bit [17]: 1 for individual sectors of block 0 and block 1 using relief sectors, 0 for others.
- Bit [16]: Reserved bit, fixed to 0.
- Bits [15:0]: Address [19:4].

Relief Sectors: Block 0 and block 1 each have 2 additional sectors used to replace defective sectors found during mass production testing.

#### 8.3.7.2 ECC Error

Block 0 and block 1 each have 2 ECC error record registers and 1 ECC error overflow flag bit.

If an ECC error occurs, it will first set ERR0. If ERR0 is not cleared and a new ECC error occurs, it will set ERR1. If both ERR0 and ERR1 are active and a new ECC error occurs, EFM\_FSR.ECEROF0/1 will be set. Therefore, customers need to clear the error record registers in a timely manner.

#### 8.3.7.3 Error Injection Read

Customers can intentionally set data errors by setting the error injection read mode, which can be used for ECC logic self-test.

Error injection read mode setup steps are as follows:

1. Disable the Flash register write protection. (Write 0x0123 to EFM\_FAPRT, then write 0x3210)
2. Set ECC verification enabled. (Example: EFM\_CKPR=0x77, EFM\_CKCR=0x03000300)
3. Set error injection read mode. (EFM\_EIEN.F0\_EIEN/F1\_EIEN=1)
4. Write data to EFM\_F0EIR/F1EIRn (n=0-4).
  - In the above registers, only 1 bit can be set to "1" to check for one-bit ECC errors.
  - 2 bits can be set to "1" to check for two-bit ECC errors.
5. Read the programmed Flash address.
6. Check the EFM\_CKSR, EFM\_FSR, EFM\_F0ERRn, EFM\_F1ERRn (n=0/1) registers.
7. Set back to Normal read mode. (EFM\_EIEN.F0\_EIEN/F1\_EIEN=0)

The above procedure should be executed on a different Flash block from the check address, or on other memory (e.g., RAM).

### 8.3.8 Interrupt

The EFM module has 3 interrupts: PE (program/erase) error interrupt, bus conflict interrupt, and operation end interrupt, which can be queried by reading the EFM\_FSR register status flag bits.

#### 1. PE error interrupt EFM\_PEERR:

- **Position:**

- ▶ When a programming, erasing, or full erasing operation is performed on a latched OTP address (EFM\_FSR.OTPWERR0=1).
- ▶ After the OTP function is enabled, the space from 0x03000000 to 0x03001FFF is erased, with the full erase operation (EFM\_FSR.OTPWERR0=1).
- ▶ Issue program, erase, and full erase operations to write-protected sectors (EFM\_FSR.PRTWERR0/1=1).
- ▶ The programming address is not 4-byte aligned or the data size is not 32 bits (EFM\_FSR.PGSZERR0/1=1).  
If the programming addresses with the last bit of 0x0, 0x4, 0x8, 0xC are not written consecutively (EFM\_FSR.PGSZERR0/1=1).
- ▶ In single programming Read-Back mode, the hardware automatically reads a value from the programming address that is inconsistent with the written value (EFM\_FSR.MISMTCH0/1=1).

- **Clear:**

Write 1 to the corresponding flag clear bit in the EFM\_FSCLR register to clear the status bit.

#### 2. Flash read and write conflict interrupt EFM\_COLERR:

- **Position:**

- ▶ During the Flash busy period (EFM\_FSR.RDY0=0 or EFM\_FSR.RDY1=0), read and write operations are performed on the Flash block. (Continuous programming mode, except for continuous writing to Flash)

- **Clear:**

Write 1 to the corresponding flag clear bit in the EFM\_FSCLR register to clear the status bit.

#### 3. End of operation interrupt EFM\_OPTEND:

- **Position:**

- ▶ Programming mode: End of programming for a single address (EFM\_FSR.OPTEND0/1=1).
- ▶ Erase mode: Sector erase, full erase end (EFM\_FSR.OPTEND0/1=1).

- **Clear:**

Write 1 to the corresponding flag clear bit in the EFM\_FSCLR register to clear the status bit.

## 8.4 Register Description

### 8.4.1 Register List

Base Address: 0x40010400

Table 8-4 Embedded Flash Memory (EFM) Register Offset

| Offset | Register     | Description                        | Width |
|--------|--------------|------------------------------------|-------|
| 0x0000 | EFM_FAPRT    | Flash Access Protect Register      | 32    |
| 0x0004 | EFM_KEY1     | Flash Key 1 Register               | 32    |
| 0x0008 | EFM_KEY2     | Flash Key 2 Register               | 32    |
| 0x0014 | EFM_FSTP     | Flash Stop Register                | 32    |
| 0x0018 | EFM_FRMC     | Flash Read Mode Register           | 32    |
| 0x001C | EFM_FWMC     | Flash Write Mode Register          | 32    |
| 0x0020 | EFM_FSR      | Flash State Register               | 32    |
| 0x0024 | EFM_FSCLR    | Flash State Clear Register         | 32    |
| 0x0028 | EFM_FITE     | Flash Interrupt Enable Register    | 32    |
| 0x002C | EFM_FSWP     | Flash Boot Swap Status Register    | 32    |
| 0x0030 | EFM_FRMC2    | Flash Read Mode Register 2         | 32    |
| 0x0040 | EFM_CHIPID   | Chip Identification Register       | 32    |
| 0x0050 | FEM_UQID0    | UNIQUE ID Register 0               | 32    |
| 0x0054 | EFM_UQID1    | UNIQUE ID Register 1               | 32    |
| 0x0058 | EFM_UQID2    | UNIQUE ID Register 2               | 32    |
| 0x0180 | EFM_WLOCK    | Flash Write Lock Register          | 32    |
| 0x0190 | EFM_FONWPRT0 | Flash0 Write Protection Register 0 | 32    |
| 0x0194 | EFM_FONWPRT1 | Flash0 Write Protection Register 1 | 32    |
| 0x0198 | EFM_FONWPRT2 | Flash0 Write Protection Register 2 | 32    |
| 0x019C | EFM_FONWPRT3 | Flash0 Write Protection Register 3 | 32    |
| 0x01A0 | EFM_F1NWPRT0 | Flash1 Write Protection Register 0 | 32    |
| 0x01A4 | EFM_F1NWPRT1 | Flash1 Write Protection Register 1 | 32    |
| 0x01A8 | EFM_F1NWPRT2 | Flash1 Write Protection Register 2 | 32    |
| 0x01AC | EFM_F1NWPRT3 | Flash1 Write Protection Register 3 | 32    |
| 0x0350 | EFM_CKCR     | Flash Check Control Register       | 32    |
| 0x0354 | EFM_CKPR     | Flash Check Protection Register    | 32    |

| Offset        | Register                    | Description                                          | Width |
|---------------|-----------------------------|------------------------------------------------------|-------|
| 0x0358        | <a href="#">EFM_CKSR</a>    | Flash Check Status Register                          | 32    |

| 0     | F0_1ERR  | ECC 1-bit error flag for Flash block 0 | Write 1 to the flag, write 0 has no effect<br>Read:<br><ul style="list-style-type: none"> <li>0b0: No 1-bit ECC errors</li> <li>0b1: 1-bit ECC error occurs</li> </ul> | RW     |

**Note**

When confirming and clearing EFM\_CKSR, it is recommended to confirm and clear EFM\_FSR.ECEROF0/1, EFM\_F0ERRn (n=0-1), and EFM\_F1ERRn (n=0-1) together to ensure that these registers are updated synchronously to reflect the latest results.

A 2-bit error in the related information of the 20-bit address is classified as a two-bit error in the description of this register.

### 8.4.32 Flash0 Error Record Register n (EFM\_F0ERRn) (n=0-1)

The EFM\_F0ERR0 register indicates the type of ECC error 0 and the address index (offset) of this error.

The EFM\_F0ERR1 register indicates the type of ECC error 1 and the address index (offset) of this error.

Offset: 0x0378+0x04\*n

| Offset | Bit Position |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |          |       |       |   |

| 0     | VALID    | Register content is enable          | <ul style="list-style-type: none"> <li>0b0: Disable</li> <li>0b1: Enable</li> </ul>                                                                                                                                                                                                                                                               | RW     |

- FATAL=0, VALID=1: Detect a single-bit error in 128-bit data and 9-bit ECC.
- FATAL=1, VALID=1: Detect a single-bit error in the 20-bit address-related information, and two-bit errors in 128-bit data, 9-bit ECC, and 20-bit address-related information are detected.
- EFM\_FSR.ECEROF0=1: When EFM\_F0ERR0.VALID=1 and EFM\_F0ERR1.VALID=1, another new ECC error occurs.

#### Note

To clear the fatal error, set Bit[1] to 1 and Bit[0] to 0.

To clear the correctable error, set Bit[0] to 0.

If this register contains information about correctable errors, the INDEX[19:0] bit field is to be cleared after setting Bit[0] and Bit[1] in this register to 0. If Bit[1] is set to 1 and Bit[0] is set to 0, the INDEX[19:0] bit field is always cleared.

### 8.4.36 Flash1 Error Log Register n (EFM\_F1ERRn) (n=0-1)

The EFM\_F1ERR0 register indicates the type of ECC error 0 and the address index (offset) of this error.

The EFM\_F1ERR1 register indicates the type of ECC error 1 and the address index (offset) of this error.

Offset: 0x03B8+0x04\*n

| Offset | Bit Position |    |    |    |    |    |    |    |       |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |          |       |       |   |   |   |   |   |

| 0     | VALID    | Register content is enable          | <ul style="list-style-type: none"> <li>0b0: Disable</li> <li>0b1: Enable</li> </ul>                                                                                                                                                                                                                                                                       | RW     |

- FATAL=0, VALID=1: Detect a single-bit error in 128-bit data and 9-bit ECC.
- FATAL=1, VALID=1: Detect a single-bit error in the 20-bit address-related information, and two-bit errors in 128-bit data, 9-bit ECC, and 20-bit address-related information are detected.
- EFM\_FSR.ECEROF1=1: When EFM\_F1ERR0.VALID=1 and EFM\_F1ERR1.VALID=1, another new ECC error occurs.

#### Note

To clear the fatal error, set Bit[1] to 1 and Bit[0] to 0.

To clear the correctable error, set Bit[0] to 0.

If this register contains information about correctable errors, the INDEX[19:0] bit field is to be cleared after setting Bit[0] and Bit[1] in this register to 0. If Bit[1] is set to 1 and Bit[0] is set to 0, the INDEX[19:0] bit field is always cleared.

### 8.4.37 Flash1 Error Injection Bit Enable Register n (EFM\_F1EIRn) (n=0-4)

| 31:0 | EIR[i]<br>(i=31-0) | Error injection bit enable (inject ECC errors into Flash data in error injection read mode) | <ul style="list-style-type: none"> <li>0b0: No error is injected into Bit[n*32+i] of the Flash read data</li> <li>0b1: Errors are injected into Bit[n*32+i] of the Flash read data</li> </ul> | RW     |

#### Note

For the EFM\_F1EIR4 register:

- Bit[31:12]: Address-related bits for Flash.
- Bit[11:9]: Reserved.
- Bit[8:0]: ECC bits for Flash.

## 8.5 Precautions

1. When erasing and writing to Flash, resetting or erasing/writing operation can forcibly stop the action and the Flash data cannot be guaranteed. Users can perform only after disabling the reset and erasing the address.
2. After the erase/write operation is completed, the hardware circuit automatically reset the cache loop.
3. Repeated programming on the same address cannot ensure the correctness of the data.
4. In continuous programming mode, the Flash analog circuit is in a high-voltage state. A long-term high-voltage state can affect the Flash features. Once continuous programming is completed, exit immediately. MCU is not disabled to enter low power mode (Sleep mode, Stop mode, Power-down mode) in continuous programming mode.
5. When using the read acceleration cache, ensure that the cache RAM does not power down.  
(PWC\_PRAMLPC.PRAMPDC2=0)
6. When the bus is in release state (EFM\_FWMC.BUSHLDCTL=1) during programming and erasing, set the vectors and subroutines to RAM or Flash blocks other than those being programmed or erased.
7. When ECC check is enabled and the unprogrammed addresses with 128-bit data and 9-bit ECC are all "1", ECC correction and detection are not guaranteed if errors occur.

## 9 Built-in SRAM (SRAM)

### 9.1 Introduction

This product has 512KB system SRAM (SRAMH/SRAM1/SRAM2/SRAM3/SRAM4) and 4KB backup SRAM (Ret SRAM).

Each SRAM can be accessed as a byte, half-word (16 bits), or full-word (32 bits). High-speed SRAM (SRAMH) read and write operations can be performed at the fastest CPU speed (240MHz) with 0 wait (i.e. 1 period), and wait periods can also be inserted. The wait period for read and write accesses to each SRAM is set by the SRAM Wait Control Register (SRAM\_WTCR).

Ret SRAM can provide 4KB of data retention space in Power-down mode.

SRAM1, SRAM2, SRAM3, SRAM4, SRAMH and Ret SRAM have ECC check. The ECC check is a one-correction-two-check code, which can correct one-bit error in the read data and address, or check 2-bit errors.

## 9.2 Functional Description

### 9.2.1 Waiting Period

The relationship between the waiting period for read and write access of each SRAM and the CPU clock frequency is as shown in the following table:

**Table 9-1 Relationship Between Waiting Period Setting of SRAM Read and Write Access and CPU Clock Frequency**

| Waiting Periods (CPU Access Periods) | Access to High-speed SRAM (SRAMH) Allowed CPU Clock Frequency Range | CPU Clock Frequency Range Allowed for Accessing the Power-down Mode Backup SRAM (Ret SRAM) | Access to Other SRAM (SRAM1, 2, 3, 4) Allowed CPU Clock Frequency Range |
|--------------------------------------|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| 0wait (1 CPU access periods)         | 0-240MHz                                                            | 0-120MHz                                                                                   | 0-200MHz                                                                |

## 9.2.2 SRAM Space Allocation

Table 9-2 SRAM Space Allocation

| Name     | Capacity | Address Range         | Check Mode |
|----------|----------|-----------------------|------------|
| SRAM1    | 128KB    | 0x20000000-0x2001FFFF | ECC check  |
| SRAM2    | 128KB    | 0x20020000-0x2003FFFF | ECC check  |
| SRAM3    | 96KB     | 0x20040000-0x20057FFF | ECC check  |
| SRAM4    | 32KB     | 0x20058000-0x2005FFFF | ECC check  |
| Ret SRAM | 4KB      | 0x200F0000-0x200FFFFF | ECC check  |
| SRAMH    | 128KB    | 0x1FFE0000-0x1FFFFFFF | ECC check  |

## 9.2.3 ECC Check Error Injection

The ECC in SRAM includes an error injection feature that can inject errors into 32-bit data and 7-bit redundancy code. Based on the configuration of the SRAM error injection enable register and the SRAM error injection bit enable register, the hardware circuit will invert the SRAM read data bit by bit to achieve error injection. Through the SRAM error injection bit enable register configuration, both 1-bit and multi-bit errors can be injected. Since the ECC circuit can only detect errors up to 2-bit, errors involving 3-bit or more may not be detected.

Figure 9-1 Error Injection Diagram for SRAM 39-bit

**Note**

0x20000000-0x20000002 does not support error injection.

The ECC in the internal CACHE RAM also includes an error injection feature that can inject errors into 128-bit data and 9-bit redundancy code. According to the configuration of the RAM error injection enable register and SRAM error injection bit enable register, the hardware circuit will invert the RAM read data bit by bit to perform error injection. Through the RAM error injection bit enable register configuration, both 1-bit and multi-bit errors can be injected. Since the ECC circuit can only detect errors up to 2-bit, errors involving 3-bit or more may not be detected.

Figure 9-2 Error Injection Diagram for CACHE RAM 137-bit

## 9.3 Register Description

### 9.3.1 Register List

Base address: 0x40050800

Table 9-3 Built-in SRAM (SRAM) Register Offset

| Offset | Register         | Description                                 | Width |
|--------|------------------|---------------------------------------------|-------|
| 0x00   | SRAMC_WTCR       | SRAM Wait Time Control Register             | 32    |
| 0x04   | SRAMC_WTPR       | SRAM Wait Time Protect Register             | 32    |
| 0x08   | SRAMC_CKCR       | SRAM Check Control Register                 | 32    |
| 0x0C   | SRAMC_CKPR       | SRAM Check Protect Register                 | 32    |
| 0x10   | SRAMC_CKSR       | SRAM Check Status Register                  | 32    |
| 0x14   | SRAM1_EIEN       | SRAM1 Error Injection Enable Register       | 32    |
| 0x18   | SRAM1_EIBIT0     | SRAM1 Error Injection Bit Enable Register 0 | 32    |
| 0x1C   | SRAM1_EIBIT1     | SRAM1 Error Injection Bit Enable Register 1 | 32    |
| 0x20   | SRAM1_ECCERRADDR | SRAM1 Error Address Register                | 32    |
| 0x24   | SRAM2_EIEN       | SRAM2 Error Injection Enable Register       | 32    |
| 0x28   | SRAM2_EIBIT0     | SRAM2 Error Injection Bit Enable Register 0 | 32    |
| 0x2C   | SRAM2_EIBIT1     | SRAM2 Error Injection Bit Enable Register 1 | 32    |
| 0x30   | SRAM2_ECCERRADDR | SRAM2 Error Address Register                | 32    |
| 0x34   | SRAM3_EIEN       | SRAM3 Error Injection Enable Register       | 32    |
| 0x38   | SRAM3_EIBIT0     | SRAM3 Error Injection Bit Enable Register 0 | 32    |
| 0x3C   | SRAM3_EIBIT1     | SRAM3 Error Injection Bit Enable Register 1 | 32    |
| 0x40   | SRAM3_ECCERRADDR | SRAM3 Error Address Register                | 32    |
| 0x44   | SRAM4_EIEN       | SRAM4 Error Injection Enable Register       | 32    |
| 0x48   | SRAM4_EIBIT0     | SRAM4 Error Injection Bit Enable Register 0 | 32    |
| 0x4C   | SRAM4_EIBIT1     | SRAM4 Error Injection Bit Enable Register 1 | 32    |
| 0x50   | SRAM4_ECCERRADDR | SRAM4 Error Address Register                | 32    |
| 0x54   | SRAMH_EIEN       | SRAMH Error Injection Enable Register       | 32    |
| 0x58   | SRAMH_EIBIT0     | SRAMH Error Injection Bit Enable Register 0 | 32    |
| 0x5C   | SRAMH_EIBIT1     | SRAMH Error Injection Bit Enable Register 1 | 32    |
| 0x60   | SRAMH_ECCERRADDR | SRAMH Error Address Register                | 32    |
| 0x64   | SRAMB_EIEN       | Ret SRAM Error Injection Enable Register    | 32    |

| Offset | Register                         | Description                                    | Width |

| 7:1  | WTPRKW   | Write Key                                | When WTPRC needs to be set to 1 or cleared to 0, 0x3B must be written to WTPRKW at the same time                                                                                                                                                                                                                                                                                                                                                                       | RW     |
| 0    | WTPRC    | SRAM Wait Control Register Write Control | <ul style="list-style-type: none"> <li>0b0: SRAM wait control register write disabled</li> <li>0b1: SRAM wait control register write enabled</li> </ul> <div>  <b>Note</b><br/>           This bit controls the write operation of the SRAMC_WTCR register. When WTPRC is 1, writing to SRAMC_WTCR is allowed; when WTPRC is 0, writing to SRAMC_WTCR is prohibited.         </div> | RW     |

**Note**

Writing 0x00000077 to this register can set WTPRC to 1; writing 0x00000076 can clear WTPRC to 0.

## 9.3.4 SRAM Check Control Register (SRAMC\_CKCR)

**Note**

In the case where RAM ECC checking is enabled, when accessing data, the used RAM space must be initialized on a word basis.

| 12:0  | ECCERRADDR | Check Error Address | Record the offset when CACHERAM generates a 1-bit or 2-bit ECC error | RO     |

## 9.4 Precautions

1. In the case where the RAM ECC check error is enabled to occur, the RAM space used must be initialized in units of words when accessing data. When executing instructions from the SRAMH space, the area of the used RAM space+3 words must be initialized in word units.
2. The VBAT domain needs to be initialized before using the backup SRAM. For the initialization method, refer to the relevant description in the "Battery Backup Power Domain" section of "Power Control (PWC)".
3. SRAM1 addresses 0x20000000, 0x20000001, and 0x20000002 do not support ECC checking. If these three addresses are accessed across regions, address 0x20000003 will not be accessed. In ECC mode, if these three addresses are accessed without cross-region access, address 0x20000003 will be accessed.
4. When the ECC mode is enabled, ECC calculation is performed on a word basis, so when accessing a byte or half-word, the SRAM controller will automatically access the corresponding word, and then read and write the byte or half-word through internal processing.
5. Because the CPU handles the CPU-I/CPU-D bus differently from the CPU-S bus, when a NOP instruction is inserted, the CPU-I/CPU-D bus and the CPU-S bus will produce different idle beats, and it is also related to the clock configuration. Normally, more than one NOP instruction must be inserted for the CPU-S bus to produce an idle beat, but only one NOP instruction needs to be inserted for the CPU-I/CPU-D bus to produce an idle beat. When error injection is enabled, when writing and reading the same address back-to-back, the write and read operations must be separated by at least 2 HCLK periods. The software can insert the interval by methods such as inserting NOP instructions. If the interval time is not enough, ECC errors may not be generated during the read operation.

## 10 General-Purpose I/O (GPIO)

### 10.1 Introduction

Some of the abbreviations used in this chapter are:

- Px (x=A to I) represents a group of ports, such as PA represents a group of 16 I/O ports PA0-PA15.
- Pxy (x=A-H, y=0-15; x=I, y=0-13, the same below) represents a single I/O port. such as the PB10 port represents the 11th I/O in the PB group.
- General Purpose Input Output (GPIO).
- NOD (Nmos Open Drain) NMOS open drain output mode.

### 10.2 Features

- Each port group has 16 I/O pins, which may be less than 16 depending on actual configuration
- Support pull-up input
- Support push-pull, open-drain output mode
- Support high, medium and low drive modes
- Supports free switching between CMOS/Schmitt input modes
- Support for external interrupt input
- Support I/O pin peripheral function multiplexing, one I/O pin can have up to 64 optional multiplexing functions
- Individual I/O pins can be programmed independently
- Each I/O pin can select 2 functions to be enable at the same time (does not support 2 output functions to be enable at the same time)

## 10.3 Functional Description

### 10.3.1 Function Block Diagram

Figure 10-1 Port Basic Structure Diagram

For detailed GPIO port number, 5V tolerant, and drive capability configuration, please refer to the "Pin Definitions" chapter in the "Datasheet".

### 10.3.2 General Input/Output GPIO Function

#### General Input Function GPI

Each I/O has a general-purpose input GPI function, and when the digital function disable bit PCRxy.DDIS is 0, the GPI function is always enable, regardless of the setting value of PFSRxy.FSEL. The status of the current port can be obtained by accessing port input data register PIDRx. The corresponding single I/O port status can also be queried through the register PCRxy.PIN, and the PIDRx.PINy register bit is equivalent to the PCRxy.PIN bit.

By default, I/O input MOS is turned off to reduce power consumption. Only when PIDRx is read, PCRxy register is opened. If required, you can also set the register PINAER.PINAEx to 1 to keep the I/O input MOS in the open state.

When the system runs at a high-speed clock and PINAER is set to 0, the input status value may not be read correctly in a single period due to the delay of the I/O input. At this time, it is necessary to set the register PCCR.RDWT and insert several wait periods. For details, refer to the description of the PCCR register.

## General Output Function GPO

Except for input-specific ports, other I/O ports have general output GPO capabilities. The GPO function can be enabled by setting the port function selection register PFSRxy.FSEL to 0x0.

When the GPO function is active, the output value can be controlled by setting the generic output permission register POERx to enable or disable the output of I/O and the generic output data register PODRx. The output values of I/O can also be controlled using the following three registers: PORRx register, POSRx register, and POTRx register. Writing 1 to the corresponding bits in the register can make the corresponding I/O output 0, 1, invert. I/O output status does not change at write 0.

The registers above are operated by 16 PORT groups. For easy control of a single I/O, I/O output can also be allowed or disabled by setting PCRxy.POUTE, where the PCRxy.POUTE register bit is equivalent to POERx.POUTE<sub>y</sub>. The output value of I/O can be controlled by setting PCRxy.POUT, where the PCRxy.POUT register bit is equivalent to PODRx.POUT<sub>y</sub>. PCRxy is suitable for controlling a single PORT and POERx/PODRx is suitable for controlling an 16-bit set of PORTs.

After the system is reset, except for the JTAG multiplexing ports PA13, PA14, PA15, PB3, PB4, and the sub-oscillator multiplexing ports PC14 and PC15, the initial functions of other ports are GPO (PFSRxy.FSEL=0x0) and are in high-impedance state (output disabled POUTE=0).

### Note

Port PI13 is multiplexed with MD. When the reset port NRST is released, PI13/MD must be fixed to a low level so that the system can enter user mode. After the mode is established, PI13 can be used as a normal IO.

## 10.3.3 Peripheral Function

Through the register PFSRxy.FSEL, each port can configure up to 64 functions. These include the generic output GPO function corresponding to FSEL=0x0. For the specific functions of each port configuration, please refer to the "Pin Definitions-Pin Function Description" in the "Datasheet".

JTAG/SWD debug function, use the register PSPCR to select. PSPCR.SPFE[z], when z=0-4 is 1, the PFSRxy.FSEL bit of the corresponding port is disabled, that is, the priority of SPFE is higher than that of FSEL. The initial value of the PSPCR register is 0x1F, and the JTAG/SWD function is enable. If you want to set these ports as functions other than JTAG/SWD, you need to write 0 to the corresponding SPFE[z] bit first.

## 10.3.4 Dual Peripheral Function

In some applications, it is necessary to set a port to two functions at the same time. In this case, you can first select a function by PFSRxy.FSEL, then select the second function by setting the common control register PCCR.BFSEL, and set PFSRxy.BFE to 1. For example: set PFSRxy.FSEL=0x2, PCCR.BFSEL=0x5, PFSRxy.BFE=0x1, then function 2 and function 5 on Pxy will be enable at the same time. It is forbidden to enable 2 output functions on the same port at the same time.

## 10.3.5 Event Port Input and Output Functions

Support 4 groups of Event Ports, each with 16 ports. Event Port1 includes EVNTP100-EVNTP115, Event Port2 includes EVNTP200-EVNTP215, and so on. EVNTPmn (m=1-4, n=0-15) The port can be used as a trigger source to trigger other peripheral devices (such as TIMER, ADC, DMA, etc.) to start specific actions according to the event generated by the port input. It can also be used as a triggered object to accept events and automatically input or output.

As a trigger source, set PEVNTRISRm, PEVNTFALRm, PEVNTNFCR to select rising edge or falling edge detection, and digital filter function, and set the function selection register PFSRxy to select EVNTPmn function. When the selected edge is entered from the port, the event EVENT\_PORTm is generated and output to other peripheral devices to trigger its start action.

As the triggered object, set AOS Modules PEVNT\_TRGSEL12/PEVNT\_TRGSEL34 to select the trigger event source, and set PEVNTDIRRm to select the output or input function. When the output function is selected, EVNTPmn outputs the specified level or flips according to the setting values of PEVNTODRm, PEVNTORRm, and PEVNTOSRm when the selected event occurs. When the input function is selected, the EVNTPmn input state is saved into the register PEVNTIDRm when the selected event occurs.

When using the Event Port function, it is necessary to first set the automatic operation system AOS function enabled bit of the function clock control 0 register (PWC\_FCG0) to active.

### 10.3.6 External Interrupt EIRQ Input Function

Except for the PI13/MD pin, each I/O port has an external interrupt input function. When the PCRxy.INTE bit is set to 1, this I/O will be enabled as the external interrupt source EIRQy input (for example: PA0 corresponds to EIRQ0, PA2 corresponds to EIRQ2). Each EIRQy can be configured with more than one I/O. Please do not allow multiple I/O inputs simultaneously for each EIRQy. The EIRQy input function and the peripheral functions selected by PFSRxy.FSEL (including GPIO) can be enable at the same time.

When I/O port is used as external interrupt EIRQ, I/O port needs to combine with interrupt controller INTC, set filter, interrupt trigger edge, interrupt number and so on. For details, please refer to the relevant description in the "Interrupt Controller (INTC)" chapter.

### 10.3.7 Analog Function

Some I/O ports have analog input and output functions (including primary and secondary oscillators). When used as an analog function, please write 1 to the register PCRxy.DDIS to disable the digital function of the current port.

### 10.3.8 General Control

The general control functions described below are independent of the specific function selected for the port, i.e., the setting of PFSRxy.FSEL, unless otherwise specified.

#### Pull Up Resistor

Each I/O port has an internal pull-up resistor. The PCRxy.PUU bit of the register can be set to allow this function. When there is no input to the I/O port, the internal part is in a weak pull-up state. Pull-up is automatically disable when the I/O port is in the output state.

#### Note

When the I/O port selects the I2Cx\_SCL/I2Cx\_SDA function, the setting of the register PUU will be ignored, and the internal pull-up function will be forced to be disable.

The PA11/USBFS\_DM, PA12/USBFS\_DP, PB14/USBHS\_DM and PB15/USBHS\_DP pins are multiplexed with the USB port. All four pins have built-in pull-down resistors of approximately 400kΩ and are always enable.

#### Drive Capability Control

Each I/O port has 3 levels of high, medium and low drive capability adjustable, and the register PCRxy.DRV can be set as required.

This feature is only enable if the port is in the output state.

### Open-drain Output Mode

Set the PCRxy.NOD bit to set the I/O port to NMOS open-drain output mode. When NOD is active, the corresponding port can output 0 normally, and the port will be in high resistance state when output 1.

When the I/O port selects the I2Cx\_SCL/I2Cx\_SDA function, the setting of the register NOD will be ignored, and the open-drain output mode is forced to be enable.

### CMOS/Schmitt Input Mode

Each I/O port supports two input modes: CMOS and Schmitt. You can set the register PCRxy.CINSEL bit option, setting it to 0 means Schmitt input, and setting it to 1 means CMOS input. The default is Schmitt input.

When using the I/O input function, please set the input type according to actual needs.

## 10.4 Register Description

Except for Event Port related registers which only support 32-bit access, other registers support 16-bit and 32-bit access but not 8-bit access. These registers are combined as follows for 32-bit access:

Table 10-1 PORT Register List for 32-bit Access

| Address                  | Bit31 ... Bit16 | Bit15 ... Bit0 |
|--------------------------|-----------------|----------------|
| 0x40053800+0x10*n        | Reserved        | PIDRx          |
| 0x40053804+0x10*n        | POERx           | PODRx          |
| 0x40053808+0x10*n        | PORRx           | POSRx          |
| 0x4005380C+0x10*n        | Reserved        | POTRx          |
| 0x40053BF4               | Reserved        | PSPCR          |
| 0x40053BF8               | PINAER          | PCCR           |
| 0x40053BFC               | Reserved        | PWPR           |
| 0x40053C00+0x40*n+0x04*y | PFSRxy          | PCRxy          |

### Note

Unless otherwise specified, all register offset address calculation formulas in this section are:

- x=A-H corresponds to n=0-7, y=0-15.
- x=I corresponds to n=8, y=0-13.

### 10.4.1 Register List

Base address: 0x40053800

Table 10-2 General-Purpose IO (GPIO) Register Offset

| Offset             | Register | Description                               | Width |
|--------------------|----------|-------------------------------------------|-------|
| 0x00+0x10*n        | PIDRx    | General Input Data Register (x=A to I)    | 16    |
| 0x04+0x10*n        | PODRx    | General Output Data Register (x=A to I)   | 16    |
| 0x06+0x10*n        | POERx    | General Output Enable Register (x=A to I) | 16    |
| 0x08+0x10*n        | POSRx    | General Output Set Register (x=A to I)    | 16    |
| 0x0A+0x10*n        | PORRx    | General Output Reset Register (x=A to I)  | 16    |
| 0x0C+0x10*n        | POTRx    | General Output Toggle Register (x=A to I) | 16    |

Event Port base address: 0x40010800

Table 10-3 Event Port Register Offset

| Offset           | Register   | Description                                   | Width |
|------------------|------------|-----------------------------------------------|-------|
| 0x100+0x1C*(m-1) | PEVNTDIRRm | Event Port Direction Selection Register       | 32    |
| 0x104+0x1C*(m-1) | PEVNTIDRm  | Event Port Input Data Register                | 32    |
| 0x108+0x1C*(m-1) | PEVNTODRm  | Event Port Output Data Register               | 32    |
| 0x10C+0x1C*(m-1) | PEVNTORRm  | Event Port Output Data Reset Register         | 32    |
| 0x110+0x1C*(m-1) | PEVNTOSRm  | Event Port Output Data Set Register           | 32    |
| 0x114+0x1C*(m-1) | PEVNTRISRm | Event Port Rising Edge Input Enable Register  | 32    |
| 0x118+0x1C*(m-1) | PEVNTFALRm | Event Port Falling Edge Input Enable Register | 32    |
| 0x170            | PEVNTNFCR  | Event Port Input Filter Control Register      | 32    |

#### Note

In the offset of the Event Port register, m=1-4.

### 10.4.2 General Input Data Register (PIDRx)

Offset: 0x00+0x10\*n

| Offset | Bit Position |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|--------|--------------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| -      | 15           | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| Reset  | 0xFFFF       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
| Name   | PIN15        | PIN14 | PIN13 | PIN12 | PIN11 | PIN10 | PIN9 | PIN8 | PIN7 | PIN6 | PIN5 | PIN4 | PIN3 | PIN2 | PIN1 | PIN0 |
| Access | RO           | RO    | RO    | RO    | RO    | RO    | RO   | RO   | RO   | RO   | RO   | RO   | RO   | RO   | RO   | RO   |

| Bit  | Name             | Function     | Description                                                                                                                                                                                | Access |
|------|------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 15:0 | PINy<br>(y=15-0) | Input status | Corresponding to Px15-Px0 ports respectively:<br><ul style="list-style-type: none"> <li>0b0: I/O port input state is low level</li> <li>0b1: I/O port input state is high level</li> </ul> | RO     |

#### Note

When the port digital function is not disabled (PCRxy.DDIS=0), the input status of the port can be obtained by reading this register, regardless of the setting value of the function selection register PFSRxy.FSEL.

There is no variable read value for the corresponding bit of the port.

When the port digital function is disabled (PCRxy.DDIS=1), since the I/O input MOS is in the off state, the corresponding PIN bit read value is a fixed value 0x1.

### 10.4.3 General Output Data Register (PODRx)

Offset: 0x04+0x10\*n

| Offset | Bit Position |        |        |        |        |        |       |       |       |       |       |       |       |       |       |       |
|--------|--------------|--------|--------|--------|--------|--------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| -      | 15           | 14     | 13     | 12     | 11     | 10     | 9     | 8     | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
| Reset  | 0x0000       |        |        |        |        |        |       |       |       |       |       |       |       |       |       |       |
| Name   | POUT15       | POUT14 | POUT13 | POUT12 | POUT11 | POUT10 | POUT9 | POUT8 | POUT7 | POUT6 | POUT5 | POUT4 | POUT3 | POUT2 | POUT1 | POUT0 |
| Access | RW           | RW     | RW     | RW     | RW     | RW     | RW    | RW    | RW    | RW    | RW    | RW    | RW    | RW    | RW    | RW    |

| Bit  | Name              | Function    | Description                                                                                                                                              | Access |
|------|-------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 15:0 | POUTy<br>(y=15-0) | Output Data | Corresponding to Px15-Px0 ports respectively:<br><ul style="list-style-type: none"> <li>0b0: Output low level</li> <li>0b1: Output high level</li> </ul> | RW     |

#### Note

Override this register to change the output status of the corresponding port when the I/O port is set to GPO.

### 10.4.4 General Output Enable Register (POERx)

Offset: 0x06+0x10\*n

| Offset | Bit Position |         |         |         |         |         |        |        |        |        |        |        |        |        |        |        |
|--------|--------------|---------|---------|---------|---------|---------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| -      | 15           | 14      | 13      | 12      | 11      | 10      | 9      | 8      | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
| Reset  | 0x0000       |         |         |         |         |         |        |        |        |        |        |        |        |        |        |        |
| Name   | POUTE15      | POUTE14 | POUTE13 | POUTE12 | POUTE11 | POUTE10 | POUTE9 | POUTE8 | POUTE7 | POUTE6 | POUTE5 | POUTE4 | POUTE3 | POUTE2 | POUTE1 | POUTE0 |
| Access | RW           | RW      | RW      | RW      | RW      | RW      | RW     | RW     | RW     | RW     | RW     | RW     | RW     | RW     | RW     | RW     |

| Bit  | Name                           | Function      | Description                                                                                                                                          | Access |
|------|--------------------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 15:0 | POUTE <sub>y</sub><br>(y=15-0) | Output enable | Corresponding to Px15-Px0 ports respectively:<br><ul style="list-style-type: none"> <li>0b0: Output disabled</li> <li>0b1: Output enabled</li> </ul> | RW     |

#### Note

When the I/O port is set to GPO and this register is set to 1, the PODRx setting is output to the corresponding I/O port. When this register is set to 0, the output is closed and the port is in high resistance state.

It is forbidden to set the corresponding bit of a non-existent port to 1.

### 10.4.5 General Output Set Register (POSRx)

Offset: 0x08+0x10\*n

| Offset | Bit Position |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |

|-----|-------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 1   | POUTE | Output permission | <ul style="list-style-type: none"> <li>● 0b0: Output disabled</li> <li>● 0b1: Output enabled</li> </ul> The function is consistent with the register PO-<br>ERx.POUTEy  | RW     |
| 0   | POUT  | Output data       | <ul style="list-style-type: none"> <li>● 0b0: Output low level</li> <li>● 0b1: Output high level</li> </ul> The function is consistent with the register<br>PODRx.POUTy | RW     |

**Note**

1. The reset value of the external low-speed oscillator XTAL32 (XTAL32\_IN, XTAL32\_OUT) multiplexing ports PCRC14 and PCRC15 is 0x8100.
2. When DDIS is set to 1, all digital functions of the corresponding port are forcibly disabled, including general-purpose input and output, peripheral digital input and output, pull-up/pull-down functions, and external interrupt input functions. When the port is used as an analog input, please set the DDIS bit to 1.
3. When LTE is set to 1 Output Lock active, the current output status of the port remains until LTE is written to 0. This function is mainly used when the port function is switched. To avoid system malfunction caused by unexpected burrs in port output during function switching, before the function switching, the output status of the port is latched in LTE write 1, and then the register switch function is selected. Finally, the LTE write 0 is unlatched and the port status is updated to a new function.
4. When INVE is set to 1, the input and output data of the port will be inverted, including the GPIO function and other peripheral input and output functions.
5. CINSEL is used to set the I/O input mode and affects all digital input functions such as GPI, EIRQ and peripheral inputs.

| 5:0  | FSEL     | Function selection         | For the function configuration of each port, refer to the "Pin Definitions-Pin Function Description" in Datasheet.                                                                                   | RW     |

#### Note

- I/O port can select one of several features configured on the port via FSEL. Setting FSEL to 0 means selecting Func0, setting it to 1 means selecting Func1, and so on. Setting it to 15 means selecting Func15. The general output function GPO corresponding to Func0.
- The initial state of PA13, PA14, PA15, PB3, and PB4 ports is that the JTAG/SWD function is enable after reset. When configuring the FSEL selection function, it is necessary to write 0 to the corresponding bit of the register PSPCR to inactiveate the JTAG/SWD function. After reset, the PC14 and PC15 ports serve as interfaces for the external low-speed oscillator, and they are initially in a state where digital functions are disabled. To select digital functions, first, set the register CMU\_XTAL32CR.XTAL32STP to 1 to turn off the external low-speed oscillator, and then write 0 to the corresponding register PCRxy.DDIS bit to enable the digital functions.

| 15:0  | RIS[15:0] | Rising Edge Detection Per-mission | <ul style="list-style-type: none"><li>0b0: EVNTPmn rising edge event detection disabled</li><li>0b1: EVNTPmn rising edge event detection enabled</li></ul> PEVNTRISRm.RIS[n] corresponds to EVNTPmn | RW     |

 **Note**

Event Port is used as an event source. When the RIS bit is set to 1, the event is output corresponding to the rising edge of the EVNTPmn input to trigger other peripherals. The edge events of EVNTPm0-15 are combined into one event EVENT\_PORTm output, and any one of the ports will output the event EVENT\_PORTm after detecting the edge.

### 10.4.20 Event Port Falling Edge Input Enable Register (PEVNTFALRm)

Offset:  $0x118 + 0x1C * (m-1)$

| 15:0  | FAL[15:0] | Falling Edge Detection Permission | <ul style="list-style-type: none"> <li>0b0: EVNTPmn falling edge event detection disabled</li> <li>0b1: EVNTPmn falling edge event detection enabled</li> </ul> PEVNTRISRm.FAL[n] corresponds to EVNTPmn | RW     |

#### Note

Event Port is used as an event source. When the FAL bit is set to 1, the event is output corresponding to the falling edge of the EVNTP input to trigger other peripherals. The edge events of EVNTPm0-15 are combined into one event EVENT\_PORTm output, and any one of the ports will output the event EVENT\_PORTm after detecting the edge.

## 10.4.21 Event Port Input Filter Control Register (PEVNTNFCR)

## 10.5 Precautions

1. Do not set the same feature to multiple ports.
2. When using the analog function, please turn off the digital function of the corresponding port (PCRxy.DDIS=0b1).
3. Please switch the port function when the output latch enabled (PCRxy.LTE=0b1) to avoid unexpected glitches on the port output during switching.

## 11 Interrupt Controller (INTC)

### 11.1 Introduction

The interrupt controller (INTC) selects an interrupt event as an interrupt request and sends it to NVIC to wake up WFI; selects interrupt event as event input (RXEV) to wake up WFE; select low power consumption mode (Sleep mode and Stop mode) of interrupt event wake-up system ; control external interrupts and software interrupts.

The main features of INTC are as follows:

1. Maskable interrupts: INTC is equipped with 457 interrupt events, which are processed and sent to NVIC as interrupt requests (IRQ). It supports 144 IRQs, each IRQ corresponds to one or more interrupt events.

#### Note

For more instructions on exception and NVIC programming, please refer to the "Arm Cortex-M4 Processor Technical Reference Manual".

2. Programmable priority of NVIC: 16 programmable priorities (4-bit interrupt priority register is used).
3. Non-maskable interrupts: Multiple system interrupt event requests can be independently selected as non-maskable interrupts, and each interrupt event is equipped with independent enable, flag and flag clear registers.
4. Equipped with 16 external pin interrupt events.
5. Equipped with multiple interrupt events, please refer to the "Interrupt Event List" for the specific number.
6. Equipped with 32 software interrupt events.
7. Interrupt wakes up system Sleep mode and Stop mode.

**Table 11-1 External Interrupt Input Pin**

| Pin Name | I/O   | Description                 |
|----------|-------|-----------------------------|
| EIRQ0    | Input | External Interrupt Event 0  |
| EIRQ1    | Input | External Interrupt Event 1  |
| EIRQ2    | Input | External Interrupt Event 2  |
| EIRQ3    | Input | External Interrupt Event 3  |
| EIRQ4    | Input | External Interrupt Event 4  |

| 0x00000270     | 156        | 140     | INTC_VSSEL140    | Register INTC_VSSEL140 shares this vector with interrupt event requests selected by enable bits. |
| 0x00000274     | 157        | 141     | INTC_VSSEL141    | Register INTC_VSSEL141 shares this vector with interrupt event requests selected by enable bits. |
| 0x00000278     | 158        | 142     | INTC_VSSEL142    | Register INTC_VSSEL142 shares this vector with interrupt event requests selected by enable bits. |
| 0x0000027C     | 159        | 143     | INTC_VSSEL143    | Register INTC_VSSEL143 shares this vector with interrupt event requests selected by enable bits. |

**Note**

For the interrupt event number selected by the INTC\_INTSEL register, see the [Interrupt Event List](#).

## 11.2.2 Interrupt Event List

Interrupt events are generated by peripherals and are called interrupt sources when they are input as IRQs; When used as RXEV input, it is called an event source; when used as a peripheral trigger event, it is called a trigger source; Interrupt events can also be used as a condition to return from low power mode.

| SN | Inter-<br>rupt<br>Event<br>No. | Modules  | Interrupt Name | Inter-<br>rupt<br>Type <sup>(1)</sup> | Inter-<br>rupt<br>Source | Trig-<br>ger<br>Source | NVIC Interrupt Request (IRQ) Number Mapping <sup>(2)</sup> |                       |                        |

#### Note

1. "P" means pulse interruption, and "L" means level interruption. The interrupt flag bit must be cleared in the interrupt handler for level interrupts.
2. INTSEL refers to the INTC\_INTSEL register, and VSSEL refers to the INTC\_VSSEL register. If the interrupt event is not configured, the number selected by the interrupt selection register has no effect.
3. AOS\_STRG is generated by software setting the INTSFTTRG.STRG bit register.

## 11.3 Functional Description

### 11.3.1 Function Block Diagram

Figure 11-1 Interrupt System Block Diagram

### 11.3.2 Non-maskable Interrupt

The non-maskable interrupt events are as follows:

- ERMU interrupt
- XTAL oscillation fault interrupt
- WDT underflow/refresh interrupt
- SWDT underflow/refresh error interrupt
- Low voltage detection PVD1 interrupt
- Low voltage detection PVD2 interrupt
- Flash ECC check error interrupt
- SRAM ECC parity error interrupt
- MPU bus error interrupt

Non-maskable interrupts have the highest priority and can select multiple interrupt events. The status of each interrupt event can be queried through the interrupt flag register (INTC\_NMIFR). Please make sure all the flag bits are "0" before the non-maskable interrupt processing exits.

When you need to use non-maskable interrupts, please set them according to the following process:

1. Configure the corresponding functions for non-maskable interrupt events.
2. Write 1 to each bit of INTC\_NMIFCR to clear the interrupt flag and prevent malfunction.

3. Set the interrupt enable register INTC\_NMIER to enable the corresponding interrupt event.

**Notice**

Once the corresponding bit of INTC\_NMIER is set to 1, it cannot be changed unless a reset occurs.

### 11.3.3 External Interruption

Equipped with 16 external interrupt events, the interrupt status can be queried through the interrupt flag register (INTC\_EIFR). When using external interrupts, follow the procedure below:

1. Configure the corresponding external pin to the external interrupt function.
2. Write 1 to the respective bits of INTC\_EIFCR to clear the interrupt flags and prevent false triggering.
3. Clear INTC\_EIRQCRx.EFEN (x=0 to 15) bit to disable the digital filter.
4. Configure INTC\_EIRQCRx.EIRQTRG bit to select the trigger edge or level; set the EISMPCLK bit to choose the digital filter sampling clock; then set the EFEN bit to enable the digital filter.

### 11.3.4 Interrupt Event Multiplexer

This interrupt controller uses a total of 144 interrupt vectors, provides 3 kinds of interrupt event request selection methods, and meets various interrupt configuration requirements through flexible combination. For specific interrupt event numbers, refer to the "[Interrupt Event List](#)".

- The First Method

There are 32 interrupt vectors, corresponding to NVIC interrupt vectors 0-31. The interrupt source is selected via interrupt/event selection registers INTC\_INTSEL0 to INTC\_INTSEL31, allowing any one of the available interrupt event requests to be chosen. Interrupt vectors 0-31 must be enabled via the INTC\_IER register.

- The Second Method

There are 96 interrupt vectors in total, corresponding to NVIC interrupt vectors 32-127, which are selected through the interrupt selection registers INTC\_INTSEL32-127. The 96 interrupt vectors are grouped into 16 groups with 6 vectors per group. Meanwhile, all interrupt event requests are also divided into 16 groups with 32 requests per group. Each of the 6 interrupt vectors in a group can select any one of the 32 requests in the corresponding interrupt event request group through the interrupt selection register.

- The Third Method

There are 16 interrupt vectors, corresponding to NVIC interrupt vectors 128-143. Interrupt event requests are enabled through INTC\_VSSEL128-143. Every 32 peripheral interrupt event requests can share one interrupt vector. By selecting the interrupt event requests with peripheral flag bits, each peripheral can request an interrupt. Refer to the [Interrupt Event List](#) NVIC vectors 128-143 column for details.

### 11.3.5 Software Interrupt

The software interrupt function can generate an interrupt request by directly writing to the software interrupt register INTC\_SWIER. A total of 32 software interrupts are available, corresponding to NVIC interrupt request numbers 0-31. Their enablement is controlled by the interrupt enable register INTC\_IER.

### 11.3.6 Event Input

NIVC interrupt requests numbered 0-31 can also be used as event inputs (RXEV) to wake up the core (WFE), with their enablement controlled by the event enable register INTC\_EVTER.

The functional block diagram of interrupt requests and event inputs is shown below:

Figure 11-2 Interrupt Request/Event Input Selection

### 11.3.7 WFE Event Management

The interrupt controller can wake up the core (WFE) through interrupt requests and event inputs.

- Interrupt Request Wake-up Core

Select an interrupt event, set INTC\_INTSEL according to the selected interrupt request and enable the INTC\_IER register (without enabling the interrupt request in NVIC). Set the INTC\_EVTER register to disabled, and enable the SEVONPEND bit in the Cortex-M4 core control register SCR. Executing WFE puts the core into Sleep mode. When the selected interrupt event occurs, the core is awakened from Sleep mode but does not enter the interrupt handler.

- Event Input Wake-up Core

Select an interrupt event, set INTC\_INTSEL according to the selected interrupt request and enable the INTC\_EVTER register. The INTC\_IER register is set to disabled. Executing WFE puts the core into Sleep mode. When the selected interrupt event occurs, the core is woken up from Sleep mode.

### 11.3.8 Noise Filter

In order to eliminate input noise, the external interrupt EIRQx (x=0-15) is configured with both digital and analog filters.

The digital filter is enabled via the INTC\_EIRQCRx.EFEN bit. The filter samples the EIRQ input signal using PCLK3 as the sampling clock. The filtering width is jointly determined by the setting value of the EIRQCR.EISMPCLK bit and NFSEL bit. The input signal is filtered out if its level is smaller than the sampling period × (NFSEL setting value + 1).

Example: When NFSEL=0x02, signals with widths less than 3 sampling periods will be filtered out. The sampling period is set by the INTC\_EIRQCRx.EISMPCLK bit.

Figure 11-3 Digital Filter Operation Diagram (taking NFSEL=0x02 as an example)

The analog filter is enabled by the INTC\_EIRQCRx.NOCEN register. After enabling, the signal is filtered with the filter width selected by the INTC\_NOCCR.NOCSEL bit.

The two filters are independent of each other and can be enabled or disabled separately. When both are enabled, the signal first passes through the analog filter and then the digital filter before entering the internal circuit.

The digital filter must be turned off before entering the Stop mode. The digital filter is enabled after returning from the Stop mode. The analog filter can work in Stop mode.

### 11.3.9 Low Power Mode Return

#### Sleep Mode Return

To wake up the CPU from Sleep mode using an interrupt request, configure the following:

- Select an interrupt event as the interrupt request.  
If using interrupt requests 0-31, configure the INTC\_IER register.
- Enable the corresponding interrupt in the NVIC.
- If using a non-maskable interrupt, configure the INTC\_NMIER register.

#### Stop Mode Return

To return from Stop mode via an interrupt request, configure the following:

- Select an interrupt event as the interrupt request.  
If using interrupt requests 0-31, configure the INTC\_IER register.
- Enable the interrupt source via the INTC\_WKEN register.  
If non-maskable interrupts are used, enable the interrupt events through the INTC\_NMIER register.  
The non-maskable interrupts that can wake up the stop mode are: XTAL oscillation fault interrupt, SWDT underflow/refresh interrupt.
- Enable the corresponding interrupt request in the NVIC.

#### Power-down Mode Return

The return from Power-down mode can be returned by the conditions described in the Power Control (PWC) section, NRST pin reset, power-on reset, and brown-out reset conditions. After returning, the CPU enters the reset interrupt processing. For detailed instructions, please refer to the relevant description in the "Power Control (PWC)" section.

#### Non-maskable Interrupt and WFI Command

Before executing the WFI instruction, please confirm that all status bits of the non-maskable interrupt flag register INTC\_NMIFR are 0.

## 11.4 Register Description

### 11.4.1 Register List

Base Address: 0x40051000

Table 11-4 Interrupt Controller (INTC) Register Offset

| Offset             | Register     | Description                                              | Width |
|--------------------|--------------|----------------------------------------------------------|-------|
| 0x0000             | INTC_NOCCR   | External Interrupt Filter Control Register               | 32    |
| 0x0004             | INTC_NMIER   | Non-maskable Interrupt Enable Register                   | 32    |
| 0x0008             | INTC_NMIFR   | Non-maskable Interrupt Flag Register                     | 32    |
| 0x000C             | INTC_NMIFCR  | Non-maskable Interrupt Flag Clear Register               | 32    |
| 0x0010+0x4*x       | INTC_EIRQCRx | External Interrupt Control Register x<br>(x=0-15)        | 32    |
| 0x0054             | INTC_EIFR    | External Interrupt Flag Register                         | 32    |

## 11.5 Precautions

For a description of ARM core interrupts, please refer to the "ARM Processor Cortex<sup>®</sup>-M4 Technical Reference Manual (ARM DDI 0439D)".

## 12 Automatic Operation System (AOS)

### 12.1 Introduction

The Automatic Operation System (AOS) is used to achieve coordination between peripherals without the assistance of the CPU. It utilizes events generated by peripherals as AOS sources, such as timer comparison matches, timer counting overflow, RTC periodic signals, various states of the sending and receiving data of the communication module (idle, receive data full, transmit data end, transmit data empty), ADC conversion end events, etc., to trigger actions of other peripherals. The triggered peripheral actions are referred to as AOS targets.

The AOS also equips 4 programmable logical units (PLUs) for logical operations between PORT and AOS sources. Users can select one or more AOS sources to trigger the same AOS target based on their needs.

### 12.2 Features

The AOS has multiple trigger sources, detailed in the [AOS Source Events](#). Unless specifically restricted, each AOS target can select one or more of these as trigger sources. When multiple trigger sources are required, the logic units (PLUs) equipped in the AOS can be used, allowing up to 4 trigger sources to be selected simultaneously. In addition, two common trigger sources can be selected through the common trigger source selection registers 1 and 2, which are shared by all AOS targets. Thus, for an AOS target, up to 6 trigger sources can be selected, and any of these can trigger the AOS target action when an event occurs.

Triggering can be done by hardware from peripheral circuits or by software through register writes.

The peripherals and their quantities that can serve as AOS targets are as follows:

- 4 DCU trigger targets
- 17 DMA trigger targets
- 1 Timer0 trigger target
- 1 Timer2 trigger target
- 4 Timer6 trigger targets
- 4 TimerA trigger targets
- 2 Event Port trigger targets
- 2 HASH trigger targets
- 1 OTS trigger target
- 3 sets of 2 ADC trigger targets for ADC1-ADC3 sequence triggering

12.3 Functional Description

12.3.1 Function Block Diagram

Figure 12-1 AOS Module Block Diagram

12.3.2 AOS Source Events and Targets

The AOS source event numbers are listed in the Interrupt Event List in the "Interrupt Controller (INTC) " chapter. Events marked with a "✓" in the "Trigger Source" column can be used as AOS sources. The AOS targets are listed in the table below.

Table 12-1 AOS Target List

| Modules | SN | Action                                                                                                            |
|---------|----|-------------------------------------------------------------------------------------------------------------------|
| DCU_1   | 0  | Trigger addition/subtraction operation, trigger data increment or decrement in triangular wave/sawtooth wave mode |

| Modules    | SN | Action                                                                                                            |
|------------|----|-------------------------------------------------------------------------------------------------------------------|
| DCU_2      | 1  | Trigger addition/subtraction operation, trigger data increment or decrement in triangular wave/sawtooth wave mode |
| DCU_3      | 2  | Trigger addition/subtraction operation, trigger data increment or decrement in triangular wave/sawtooth wave mode |
| DCU_4      | 3  | Trigger addition/subtraction operation, trigger data increment or decrement in triangular wave/sawtooth wave mode |
| DMA_1      | 4  | Trigger channel 0 starting transmission                                                                           |
|            | 5  | Trigger channel 1 starting transmission                                                                           |
|            | 6  | Trigger channel 2 starting transmission                                                                           |
|            | 7  | Trigger channel 3 starting transmission                                                                           |
|            | 8  | Trigger channel 4 starting transmission                                                                           |
|            | 9  | Trigger channel 5 starting transmission                                                                           |
|            | 10 | Trigger channel 6 starting transmission                                                                           |
|            | 11 | Trigger channel 7 starting transmission                                                                           |
| DMA_2      | 12 | Trigger channel 0 starting transmission                                                                           |
|            | 13 | Trigger channel 1 starting transmission                                                                           |
|            | 14 | Trigger channel 2 starting transmission                                                                           |
|            | 15 | Trigger channel 3 starting transmission                                                                           |
|            | 16 | Trigger channel 4 starting transmission                                                                           |
|            | 17 | Trigger channel 5 starting transmission                                                                           |
|            | 18 | Trigger channel 6 starting transmission                                                                           |
|            | 19 | Trigger channel 7 starting transmission                                                                           |
| DMA_1/2    | 20 | Trigger event trigger channel reset                                                                               |
| Timer6     | 21 | Trigger counter start/stop/clear/refresh/capture/increment/decrement                                              |
|            | 22 | Trigger counter start/stop/clear/refresh/capture/increment/decrement                                              |
|            | 23 | Trigger counter start/stop/clear/refresh/capture/increment/decrement                                              |
|            | 24 | Trigger counter start/stop/clear/refresh/capture/increment/decrement                                              |
| Event Port | 25 | Trigger Event Port 1/2 action                                                                                     |
|            | 26 | Trigger Event Port 3/4 action                                                                                     |
| Timer0     | 27 | Trigger counter start/stop/clear/capture                                                                          |
| Timer2     | 28 | Trigger counter start/stop/clear/capture                                                                          |
| HASH       | 29 | Trigger HASH operation start                                                                                      |
|            | 30 | Trigger HASH final operation start                                                                                |

| Modules | SN     | Action                                                           |
|---------|--------|------------------------------------------------------------------|
| TimerA  | 31     | Trigger Unit 1/5/9 counter start/stop/clear/increment/decrement  |
|         |        | Trigger Unit 2/6/10 counter input capture                        |
|         | 32     | Trigger Unit 2/6/10 counter start/stop/clear/increment/decrement |
|         |        | Trigger Unit 1/5/9 counter input capture                         |
|         | 33     | Trigger Unit 3/7/11 counter start/stop/clear/increment/decrement |
|         |        | Trigger Unit 4/8/12 counter input capture                        |
|         | 34     | Trigger Unit 4/8/12 counter start/stop/clear/increment/decrement |
|         |        | Trigger Unit 3/7/11 counter input capture                        |
| OTS     | 35     | Trigger OTS temperature measurement start                        |
| ADC_1   | 36, 37 | Trigger sequence A/B starting analog-to-digital conversion       |
| ADC_2   | 38, 39 | Trigger sequence A/B starting analog-to-digital conversion       |
| ADC_3   | 40, 41 | Trigger sequence A/B starting analog-to-digital conversion       |

### 12.3.3 Dedicated Trigger Source

For peripheral circuit modules with AOS targets, each AOS target is equipped with a dedicated peripheral trigger source selection register. When the event number corresponding to an AOS source is written to this register, the AOS target selects this AOS source as its trigger source. When an AOS source event occurs, the event is passed to the AOS target through the AOS, and the peripheral circuit of the AOS target starts its action based on its settings.

### 12.3.4 Common Trigger Source

In addition to the dedicated peripheral trigger source selection registers for each AOS target, the AOS also configures two common trigger source selection registers (AOS\_COMTRGSEL1, AOS\_COMTRGSEL2). These are used to achieve the function of triggering one or more AOS targets with the same trigger source, or triggering the same AOS target with multiple AOS trigger sources. To use them, first set the common trigger source enable bit to active in the dedicated peripheral trigger source selection register for the AOS target, and then write the event number corresponding to the AOS source in the common trigger source selection register. When an AOS source event occurs, the event is passed to the AOS target through the common trigger source of the AOS, and the peripheral circuit of the AOS target starts its action based on its settings. When both dedicated and common trigger sources are set, up to 3 AOS sources can trigger the same AOS target simultaneously. Any of the 3 AOS sources can trigger the AOS target when an event occurs.

All AOS targets share these two common trigger sources. Therefore, when other AOS targets are not using the event selected by the common trigger source selection register, the common trigger source enable bit should be set to inactive in its dedicated peripheral trigger source selection register to prevent erroneous triggering.

### 12.3.5 Programmable Logic Unit (PLU)

The AOS is equipped with a total of 4 programmable logic units (PLUs), each with 4 inputs (PLINA, PLINB, PLINC, PLIND) and 1 output (PLOUT).

The sources of the four inputs PLINA-D can be AOS trigger sources, PORT inputs, or fixed values. The result of the logical operation can be used not only for AOS trigger target modules but also output through PORT.

Set the AOS\_PLUX\_CR.PLINySEL (x=0-3, y=A, B, C, D) bit to select the input source for PLINA-D. Set the AOS\_PLUX\_CR.PLMODE bit to select the desired logical operation.

For configurations of PLUX\_INA, PLUX\_INB, PLUX\_INC, PLUX\_IND, and PLUX\_OUT, please refer to the "Pin Function Description" chapter in the Datasheet.

### 12.4.3 DCU Trigger Source Selection Register (DCU\_TRGSELx) (x=1-4)

After selecting the hardware trigger start mode in the DCU, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the PLU Control Register (AOS\_PLU\_CR) accordingly. When the peripheral event corresponding to the number occurs, the DCU will be triggered to start and perform calculations by this event.

Each DCU unit corresponds to one register.

### 12.4.4 DMA1 Transfer Start Trigger Source Selection Register (DMA1\_TRGSELx) (x=0-7)

After enabling DMA1, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the PLU Control Register (AOS\_PLU\_CR) accordingly. When the peripheral event corresponding to the number occurs, DMA1 will be triggered to start and perform the transfer by this event.

Each data transfer channel corresponds to one register.

### 12.4.5 DMA2 Transfer Start Trigger Source Selection Register (DMA2\_TRGSELx) (x=0-7)

After enabling DMA2, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, DMA2 will be triggered to start and perform the transfer by this event.

Each data transfer channel corresponds to one register.

Offset: 0x34+0x04\*x

### 12.4.6 DMA Re-config Trigger Source Selection Register (DMA\_RC\_TRGSEL)

After enabling DMA, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR accordingly. When the peripheral event corresponding to the number occurs, DMA will be triggered to reset the channel.

DMA1 and DMA2 share this register.

### 12.4.7 Timer6 Hardware Trigger Event Selection Register (TMR6\_TRGSELx) (x=0-3)

After selecting internal trigger hardware synchronization in Timer6, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral circuit event corresponding to the number occurs, Timer6 will be triggered for hardware synchronization (including start/stop/clear/refresh/increment/decrement/input capture) by this event.

All Timer6 units share these 4 registers.

### 12.4.8 Event Port Trigger Source Selection Register (PEVNT\_TRGSEL12/PEVNT\_TRGSEL34)

Write the trigger event number to this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. The Event Port is triggered to output the specified level or latch the port status.

Event Port1/2 share the PEVNT\_TRGSEL12 register, and Event Port3/4 share the PEVNT\_TRGSEL34 register.

Offset: 0x68 (PEVNT\_TRGSEL12), 0x6C (PEVNT\_TRGSEL34)

### 12.4.9 Timer0 Hardware Trigger Event Selection Register (TMR0\_TRGSEL)

After selecting hardware trigger in Timer0, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b0100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the PLU Control Register (AOS\_PLU\_CR) accordingly. When the peripheral event corresponding to the number occurs, Timer0 will be triggered to act (including start/stop/clear/input capture) by this event.

All Timer0 units and their channels share this register.

### 12.4.10 Timer2 Hardware Trigger Event Selection Register (TMR2\_TRGSEL)

After selecting hardware trigger in Timer2, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, Timer2 will be triggered to act (including start/stop/clear/input capture) by this event.

All Timer2 units and their channels share this register.

### 12.4.11 HASH Hardware Trigger Event Selection Register (HASH\_TRGSELx) (x=A/B)

After writing data to HASH\_DR, use the HASH\_TRGSELA register to select the trigger event source to start the HASH operation. After writing the last set of data to HASH\_DR, use the HASH\_TRGSELB register to select the trigger event source to notify HASH to perform the final operation. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, HASH will be triggered to start the operation by this event.

#### Notice

Do not select trigger signals other than DMA\_BTCx (x=0-7).

Offset: 0x78 (HASH\_TRGSELA), 0x7C (HASH\_TRGSELB)

### 12.4.12 TimerA Hardware Trigger Event Selection Register (TMRA\_TRGSELx) (x=0-3)

After selecting internal hardware trigger in TimerA, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, TimerA will be triggered to act (including start/stop/clear/input capture) by this event.

All TimerA units share these 4 registers.

### 12.4.13 OTS Hardware Trigger Event Selection Register (OTS\_TRGSEL)

After selecting the hardware trigger start mode in the OTS, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, OTS will be triggered to start by this event.

### 12.4.14 ADC1 Conversion Start On-Chip Trigger Source Selection Register (ADC1\_TRGSELx) (x=0-1)

After selecting the on-chip trigger mode in ADC1, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, ADC1 will be triggered to start ADC conversion by this event.

Sequence A and sequence B of ADC1 share these 2 registers.

### 12.4.15 ADC2 Conversion Start On-Chip Trigger Source Selection Register (ADC2\_TRGSELx) (x=0-1)

After selecting the on-chip trigger mode in ADC2, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, ADC2 will be triggered to start ADC conversion by this event.

Sequence A and sequence B of ADC2 share these 2 registers.

### 12.4.16 ADC3 Conversion Start On-Chip Trigger Source Selection Register (ADC3\_TRGSELx) (x=0-1)

After selecting the on-chip trigger mode in ADC3, use this register to select the trigger event source. When PLCHSEL[2:0] is set to 0b000, write the trigger event number to the TRGSEL[8:0] bits in this register. When PLCHSEL[2:0] is set to 0b001, 0b010, 0b011, or 0b100, write the trigger event number to the corresponding PLU Trigger Source Selection Register (AOS\_PLU\_TRGSELA/B/C/D), and configure the AOS\_PLU\_CR Register accordingly. When the peripheral event corresponding to the number occurs, ADC3 will be triggered to start ADC conversion by this event.

Sequence A and sequence B of ADC3 share these 2 registers.

12.4.17 Common Trigger Source Selection Register (AOS\_COMTRGSELx) (x=1-2)

Write the trigger event number to AOS\_COMTRGSEL1/2. When the peripheral circuit event corresponding to the number occurs, if the COMEN bit in the dedicated trigger source selection register of one or more AOS targets is 1, the peripheral event corresponding to the number will trigger the start of this one or more AOS targets.

Offset: 0xAC (AOS\_COMTRGSEL1), 0xB0 (AOS\_COMTRGSEL2)

### 12.4.18 PLU Control Register (AOS\_PLUx\_CR) (x=0-3)

The AOS is equipped with a total of 4 PLUs, each with 4 inputs (PLINA, PLINB, PLINC, PLIND) and 1 output (PLOUT).

The inputs for logical operations can be AOS trigger sources or PORT inputs. Select the input source or fixed value through the PLINySEL (y=A, B, C, D) bit. Select the desired logical operation through the PLMODE bit.

| 8:0  | PLTRGSEL | Trigger source selection | Write the number of the peripheral circuit event to be selected | RW     |

## 13 Memory Protection Unit (MPU)

### 13.1 Introduction

The MPU can provide protection to the memory, and can improve the security of the system by preventing unauthorized access.

This chip has built-in 1 MPU unit for CPU, 5 MPU units for host and 1 MPU unit for IP.

**Table 13-1 MPU Module Introduction**

| Modules |                         | Content                                                                                                         |
|---------|-------------------------|-----------------------------------------------------------------------------------------------------------------|
| ARM MPU |                         | Memory Protection Unit of the CPU<br>8 areas, see ARM MPU description for details                               |
| DMPU    | System DMA_1 MPU: SMPU1 | Memory protection unit of system DMA_1<br>16 areas, 8 areas dedicated to system DMA, 8 areas shared by all DMAs |
|         | System DMA_2 MPU: SMPU2 | Memory protection unit of system DMA_2<br>16 areas, 8 areas dedicated to system DMA, 8 areas shared by all DMAs |
|         | USBFS-DMA MPU: FMPU     | Storage Protection Unit of USBFS-DMA<br>8 regions, shared by all DMAs                                           |
|         | USBHS-DMA MPU: HMPU     | Storage Protection Unit of USBHS-DMA<br>8 regions, shared by all DMAs                                           |
|         | ETH-DMA MPU: EMPU       | Storage Protection Unit of ETH-DMA<br>8 regions, shared by all DMAs                                             |
| IPMPU   |                         | Access protection unit for system IP and security-related IP                                                    |

Among them, the ARM MPU provides the access control of the CPU to the entire 4G address space.

DMPU includes SMPU1/SMPU2/FMPU/HMPU/EMPU, which respectively provide read and write access rights control of system DMA\_1/system DMA\_2/USBFS-DMA/USBHS-DMA/ETH-DMA to the entire 4G address space. When accessing the prohibited space, the MPU action can be set to ignore/bus error/non-maskable interrupt/reset.

The IPMPU provides access control to system IP and security-related IP in non-privileged mode.

## 13.2 Functional Description

### 13.2.1 Locale Setting

The MPU manages the authority of the storage space in units of regions. Each area can independently set the base address and area size, the range of which can be set is 32Bytes-4GBytes, the size must be  $2^N$  Bytes ( $N=5-32$ ), and the corresponding lower  $N$  bits of the base address are 0.

The address space not covered by any region is called the background region.

### 13.2.2 Permission Setting

Each area, including the background area, can be independently set for each DMA to allow reading/prohibit reading and allow writing/prohibit writing. If address overlap occurs between different areas, the set prohibition takes precedence.

### 13.2.3 MPU Action Selection

When a prohibited access occurs, the access has no effect (read access reads 0, write access has no effect), and the corresponding action can be set, which can be set as:

- Ignore
- Bus error
- Nomaskable interrupt
- Reset

### 13.2.4 Start MPU

SMPU1/SMPU2/FMPU/HMPU/EMPU can be enabled independently.

It is recommended to enable the MPU after setting the area range/permission setting/action selection.

## 13.3 Operation Example

### 13.3.1 Only Enable Partial Space Access

**Example:** Set the permission of the background area to read/write disable, set area 0 to read/write enable, set area 1 to read enable and disable write, and the range of area 0 covers area 1.

Figure 13-1 Schematic Diagram of Partial Memory Access Permissions

### 13.3.2 Only Disable Partial Space Access

**Example:** Set the permission of the background area to read enable/write disable, set area 0 to read/write enable, set area 1 to read enable/write disable, area 0 covers area 1, and set area 2 to read/write disable.

Figure 13-2 Schematic Diagram of only Prohibiting Access to Part of Space

## 13.4 Register Description

### 13.4.1 Register List

The registers of this module can only be set by the CPU.

Base address: 0x40050000

Table 13-2 Memory Protection Unit (MPU) Register Offset

| Offset      | Register   | Description                                           | Width |

|-------|----------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 31:16 | Reserved | Reserved                  | -                                                                                                                                                                             | -      |
| 15:1  | WKEY     | Write code                | Writing to MPUWE requires simultaneously writing 0x4B52 to the WKEY register                                                                                                  | WO     |
| 0     | MPUWE    | MPU register write enable | <ul style="list-style-type: none"> <li>0b0: MPU address registers/control registers write disable</li> <li>0b1: MPU address register/control register write enable</li> </ul> | RW     |

**Note**

Writing 0x96A5 to this register sets MPUWE to 1; writing 0x96A4 clears MPUWE to 0. It is prohibited to modify MPUWE by writing any other values.

## 13.4.6 IP Access Protection Register (MPU\_IPPR)

**Note**

1. In the privileged mode, the object IP can be read and written without being affected by this register.
2. When DMPU read/write protection is enabled, all registers except MPU\_IPPR are inaccessible for read or write operations.

| Offset | Bit Position |          |         |         |         |         |         |         |          |          |         |         |        |         |           |           |         |         |        |         |         |         |        |        |        |         |         |         |         |         |            |            |

**Note**

When multiple area settings overlap, the priority is: Setting prohibited > setting enabled.

## 14 Keyboard Scan Control Module (KEYSCAN)

### 14.1 Introduction

This product is equipped with a keyboard scan control module (KEYSCAN) 1 unit. The KEYSCAN module supports keyboard array (row and column) scanning, the column is driven by an independent scan output KEYOUT<sub>m</sub> (m=0-7), and the row KEYIN<sub>n</sub> (n=0-15) is input as EIRQ<sub>n</sub> (n=0-15) is detected. This module realizes the key recognition function through the line scan query method.

### 14.2 Features

- EIRQ0-EIRQ15 can be independently selected as the row input of the keyboard array.
- KEYOUT can be selected by register.
- Output low level sequentially at regular intervals to scan the keyboard array.
- Scan time can be set.
- Stop scanning when the EIRQ interrupt is detected, and locate the pressed key according to the SSR.INDEX value and the EIRQ interrupt flag (INTC\_EIFR.EIF).

### 14.3.1 Function Block Diagram

**Figure 14-1 KEYSKAN System Block Diagram**

| Pin Name        | Direction | Description                   |
|-----------------|-----------|-------------------------------|
| KEYINn (n=0-15) | Input     | Keyboard row input signal     |
| KEYOUTm (m=0-7) | Output    | Keyboard column output signal |

Through the register SCR.KEYINSEL[15:0], KEYIN can be independently selected from EIRQ0-EIRQ15, and through the register SCR.KEYOUTSEL[2:0], the KEYOUT pin can be selected, so that the number of rows and columns of the keyboard can be flexibly selected. It can support a keyboard array of 16 rows\*8 columns.

### 14.3.3 Keyboard Scan Function

The keyboard scan function is: output low level to the columns of the keyboard array in a continuous period, so that when a key is pressed, a corresponding EIRQ interrupt flag will be generated.

When KEYSCAN\_SER.SEN is set to 1, KEYOUT0 outputs a low level, KEYOUT1-KEYOUTn (n is set by KEYSCAN\_SCR.KEYOUTSEL[2:0]) are Hi-Z, and after the time set by KEYSCAN\_SCR.T\_LLEVEL[4:0], all KEYOUT0-KEYOUTn pins are Hi-Z. After the time set by KEYSCAN\_SCR.T\_HIZ[2:0], KEYOUT1 outputs a low level, and the other KEYOUT pins are Hi-Z, and so on. When a key is pressed and an EIRQ interrupt flag is generated, the keyboard scanning function stops, and the scanning automatically restarts after the corresponding interrupt flag is cleared.

## 14.5 Precautions

This module drives the keyboard column, and the keyboard row detection is realized by the external EIRQ function of the interrupt control module (INTC). EIRQ needs to select the falling edge detection, and open the digital filter function, and set the appropriate filter time.

If you use this function in STOP mode, you need to set the scan-related parameters and select the internal low-speed oscillator LRC or the external low-speed oscillator XTAL32 clock as the scan clock.

If the internal pull-up resistor of the chip is used, please refer to the relevant description in the "Electrical Characteristics-I/O Port Characteristics" section of the "Datasheet" to select the appropriate scan time and filter time.

## 15 Clock Trimming Controller (CTC)

### 15.1 Introduction

Clock Trimming Controller (CTC) can automatically calibrate internal high-speed oscillator (HRC). Due to the influence of the working environment, the frequency of HRC may deviate. Based on the external high-precision reference clock, CTC is used to automatically adjust the frequency of HRC by hardware to get an accurate HRC clock.

### 15.2 Features

- Three external reference clock sources: XTAL, XTAL32, CTCREF
- 16-bit calibration counter for frequency measurement with reload function
- 8-bit calibration deviation value and 6-bit calibration value for frequency calibration
- Error interrupt for indicating calibration failure

### 15.3 Functional Description

#### 15.3.1 Function Block Diagram

Figure 15-1 CTC Function Block Diagram

#### 15.3.2 Reference Clock

CTC has the following three reference clocks, selected through the CTC\_CR1.REFCKS bit.

- External high-speed clock (XTAL)
- External low-speed clock (XTAL32)
- External reference-speed clock (CTCREF)

Both the jitter of HRC and the counting error during calibration can affect the calibration accuracy. This can be reduced by setting the CTC\_CR1.REFPSC bit for the reference clock to select an appropriate prescaler. The error calculation formula is as follows:

$$TE = \frac{0.099\%}{\sqrt{(F_{hrc} \div F_{ref}) \times PSC_{ref} \div 10^5}} + \frac{4}{(F_{hrc} \div F_{ref}) \times PSC_{ref}}$$

Where:

- $F_{hrc}$  represents the target frequency of HRC, in Hz;
- $F_{ref}$  represents the frequency of the reference clock, in Hz;
- $PSC_{ref}$  represents the reference clock frequency division number.

The following two tables list the error values for different reference clock frequencies and prescaler conditions when the target frequency of HRC is 16MHz and 20MHz, respectively, for quick reference.

#### Note

- "Cannot be set" indicates that the setting exceeds the range of the calibration counter and calibration cannot be completed.
- "Not Recommended" indicates that the setting error exceeds 2%, so it is not recommended.

Table 15-1 Measurement Error for HRC Target Frequency of 20MHz

| $PSC_{ref}$ | $F_{ref}$     |                 |                 |                 |                 |

### 15.3.3 Frequency Calibration

After writing 1 to the CTCEN bit in the CTC\_CR1 register, the 16-bit calibration counter reloads RLDVAL from the CTC\_CR2 register and starts down-counting under the trigger of the reference clock, and the count clock is provided by HRC. After counting starts, if the reference clock triggers the count to stop, the 16-bit calibration counter will stop counting. Otherwise, the 16-bit calibration counter will continue counting and stop when the count value underflows to 0xFFFF.

Figure 15-2 CTC Calibration Diagram

After the 16-bit calibration counter stops counting, HRC frequency calibration starts. Since the calibration target deviation value  $OFSVAL$  is added when setting the calibration count reload value RLDVAL, if the value of the 16-bit calibration counter is greater than  $2 \times OFSVAL$  and no underflow occurs, it indicates that the current frequency is slower than the desired frequency, and the value of  $TRMVAL$  in the CTC\_CR1 register needs to be increased to raise the frequency. Conversely, if the value of the 16-bit calibration counter underflows, it indicates that the current frequency is faster than the desired

frequency, and the value of TRMVAL needs to be decreased to lower the frequency. If the value of the 16-bit calibration counter is less than  $2 \times \text{OFSVAL}$ , it indicates that the current frequency is within the desired frequency range, and no adjustment to TRMVAL is required.

- When Counter > (OFSVAL $\times$ 2), counting stops, and the value of TRMVAL is automatically incremented by 1.
- When  $0 \leq \text{Counter} \leq (\text{OFSVAL} \times 2)$ , counting stops, the value of TRMVAL remains unchanged, and the CTC\_STR.TRIMOK bit automatically becomes 1.
- When Counter=0xFFFF, the value of TRMVAL in the CTC\_CR1 register is automatically decremented by 1.

After each adjustment of TRMVAL, the next calibration starts automatically. Calibration stops when CTCEN is cleared by software or a calibration error occurs.

### 15.3.4 Interrupt

The mid-value of TRMVAL is 0x00. If the result of automatically adding 1 exceeds 0x1F, the value of TRMVAL remains 0x1F, and a calibration overflow error occurs. At this time, the TRMOVF bit in the CTC\_STR register automatically becomes 1. Conversely, if the result of automatic subtraction by 1 is less than 0x20, the value of TRMVAL remains 0x20, and a calibration underflow error occurs. At this time, the TRMUFD bit in the CTC\_STR register automatically becomes 1. When a calibration overflow or underflow error occurs, calibration stops automatically (CTCEN is automatically cleared). If the ERRIE bit in the CTC\_CR1 register is 1, a calibration error interrupt request is generated. For specific setting methods, please refer to the "Interrupt Controller (INTC)" chapter.

## 15.4 Operation Example

### 15.4.1 Use XTAL32 as the Reference Clock to Calibrate HRC to 20MHz with a Calibration Target Deviation of Less Than 0.5%

Set XTAL32 to a 32-division prescaler. According to [Table 15-1 : Measurement Error for HRC Target Frequency of 20MHz](#), the calibration error is 0.244%, which is less than the 0.5% calibration target deviation, so the scheme is feasible.

1. Set register CTC\_CR2=0x4CAD0062, where:
  - $\text{OFSVAL} = (20 \div 0.032768) \times 32 \times 0.5\% \approx 98$  (0x62)
  - $\text{RLDVAL} = (20 \div 0.032768) \times 32 + 98 \approx 19629$  (0x4CAD)
2. Set register CTC\_CR1=0x000000E1, where:
  - TRMVAL=0x00 (Start calibration from the mid-value)
  - CTCEN=1 (Start CTC)
  - ERRIE=1 (Enable error interrupt)
  - REFCKS=0b10 (Select XTAL32 as the reference clock)
  - REFPSC=0b001 (Select a 32-division prescaler for the reference clock)
3. After a while, confirm the status of the CTC\_STR.TRIMOK bit:
  - If TRIMOK=1, write 0 to CTCEN to stop CTC;
  - If TRIMOK=0, continue waiting for a while and repeat this step.
4. Confirm that CTC\_STR.CTCBSY=0, CTC stops, and calibration is complete.

If an error interrupt occurs during the process, it indicates that a calibration overflow or underflow has occurred due to exceeding the calibratable range, CTCEN is automatically cleared, and calibration stops. At this time, please adjust OFSVAL, RLDVAL, and the reference clock settings and try calibration again.

**Note**

Frequency calibration is started or stopped through the CTC\_CR1.CTCEN bit. Therefore, after starting frequency calibration, do not change the settings of any other registers. To modify the settings, write the CTCEN bit to 0 and confirm that the CTC\_STR.CTCBSY bit is 0 before making the modification.

## 15.5 Register Description

### 15.5.1 Register List

Base Address: 0x40049C00

Table 15-3 Clock Trimming Controller (CTC) Register Offset

| Offset | Register | Description            | Width |
|--------|----------|------------------------|-------|
| 0x00   | CTC_CR1  | CTC Control Register 1 | 32    |
| 0x04   | CTC_CR2  | CTC Control Register 2 | 32    |
| 0x08   | CTC_STR  | CTC Status Register    | 32    |

## 15.5.2 CTC Control Register 1 (CTC\_CR1)

## 16 DMA Controller (DMA)

### 16.1 Introduction

DMA is used to transfer data between memory and peripheral function modules, enabling data exchange between memories, between memory and peripheral function modules, and between peripheral function modules without CPU involvement.

### 16.2 Features

- The DMA bus is independent of the CPU bus and transmits data according to the AMBA AHB-Lite bus protocol.
- With 2 DMA control units, a total of 16 independent channels, which can independently operate different DMA transfer functions.
- The start source of each channel is configured through an independent trigger source selection register.
- 1 block per request.
- The data block is a minimum of one data and can be up to 1024 data.
- The width of each data item can be configured as 8-bit, 16-bit, or 32-bit.
- It can be configured for 1-65535 transfers or infinite transfers.
- The source address and destination address can be independently configured as fixed, incrementing, decrementing, repeated jump, or specified offset jump.
- 3 types of interrupts can be generated: block transfer completed interrupt, transfer completed interrupt, and transfer error interrupt. Each interrupt can be configured to be masked or unmasked. Among them, block transfer completed and transfer completed can be used as event outputs, serving as trigger sources for other peripheral modules.
- Support chain transfer function, enabling the transfer of multiple data blocks in a single request.
- Support channel reset triggered by external events.
- Support software-triggered start of transfer and software-triggered channel reset.
- When not in use, it can be set to stop state to reduce power consumption.
- The HPROT value in the AHB bus during DMA access can be set through a register.

## 16.3 Functional Description

### 16.3.1 DMA Block Diagram

Figure 16-1 DMA Architecture Diagram

### 16.3.2 Enabling the DMA Controller

To use DMA, you need to first write 0 to the FCG0.DMAx bit to allow DMA clock supply, and then write 1 to the DMA\_EN.EN bit. At the same time, DMA requires peripheral circuits to initiate transfers, so the FCG0.AOS peripheral circuit trigger function bit also needs to be written to 0.

When DMA is not in use or the chip needs to enter STOP mode, please set DMA\_EN.EN to 0 and write to FCG0 to turn off the DMA clock. Before setting EN to 0, please confirm that DMA\_CHSTAT.DMAACT is 0 to ensure that DMA has completed all transfers.

### 16.3.3 Channel Selection and Channel Priority

Each DMA control unit contains 8 channels, and each channel can configure the transfer function independently.

The channel priority order is: Channel 0 > Channel 1 >... > Channel 7.

When multiple channels in a DMA unit request transfer, they will be executed in priority order. But the channel that is already in transit will not be interrupted, the high priority channel will not start until the current channel transmission is complete.

### 16.3.4 Start DMA

DMA is started by requests generated by peripheral circuits, which are configured through the trigger source selection register (DMA\_TRGSELx, where x=0-7) for each channel independently. DMA can be started by writing to the DMA\_SWREQ.SWREQ register for software-triggered transfer. When a peripheral circuit generates a start request or software writes to a register to generate a start request, and DMA transfer enable is active (DMA\_EN.EN=1), and the transfer channel is in the permitted state (DMA\_CHEN.CHEN[x]=1), channel x transfer starts.

Before use, you need to set the peripheral circuit trigger function and DMA function enable bits in FCGO register to active.

### 16.3.5 Data Block

The amount of data transferred each time DMA is started is expressed in blocks. The size of the block is set by register DMA\_DTCTLx.BLKSIZE, and the maximum size that can be set is 1024 data. The data width of each is determined by DMA\_CHCTLx.HSIZE and can be 8-bit, 16-bit, or 32-bit.

### 16.3.6 Transfer Address Control

The source address and destination address of the transfer can be set to fixed, incrementing, decrementing, repeated jump, or nonSequence jump through registers.

- **Fixed:** The source address and destination address will be fixed during the transmission process.
- **Incrementing and Decrementing:** The source address and destination address increase or decrease by the value of HSIZE after each data item transfer. For example, when HSIZE is 8-bit, the address increases/decreases by 1 each time; for 16-bit, it increases/decreases by 2; for 32-bit, it increases/decreases by 4.
- **Repeating Jump:** After transferring a specified number of data items, the source and destination addresses return to their initial values. The amount of data that needs to be transferred before the address repeats the jump, that is, the size of the repeated area is set by the size of the register DMA\_RPT.
- **NonSequence Jump:** After transferring a specified number of data items, the source and destination addresses skip a specified offset. The offset for address jump and the amount of data to be transferred before jump, i.e., the size of the nonSequence zone, are set by the DMA\_SNSEQCTL/DMA\_DNSEQCTL registers. When the conditions for address repeated jump and nonSequence jump are met simultaneously, address repeated jump is executed.

### 16.3.7 Transfer Count

The total number of data blocks transferred by DMA is set by the DMA\_DTCTLx.CNT bit. The maximum number of transmissions can be set to 65535. Each time a data block is transferred, the register value decrements by 1. When the register value becomes 0, it indicates that all data transfer for the channel is completed, and the channel transfer permission bit (DMA\_CHEN.CHEN[x]) is automatically cleared, generating a transfer completed interrupt. If DMA\_DTCTLx.CNT is set to 0 at the beginning of the transfer, it means unlimited transmission, and each start requests to transmit a data block, but the channel transmission permission bit is not cleared, and the transmission completion interrupt will not be generated.

**Note**

After CHEN[x] is automatically cleared, to restart the channel, you need to reconfigure the channel configuration register and then write 1 to CHEN[x] to enable the channel. Otherwise, the subsequent transfer will start from the state at the end of the last transfer, i.e., the source/destination address will be the next address corresponding to the last transfer, and CNT will be 0 for unlimited transfer.

### 16.3.8 Chain Transmission

DMA controller has the function of linkage transmission. The chain transmission needs to configure the following 8 registers, a total of 8 words, called a descriptor which contains the source address, destination address, data control information, address control information, chain pointer and transmission control information of the chain transmission.

- DMA\_SARx
- DMA\_DARx
- DMA\_DTCTLx
- DMA\_RPTx
- DMA\_SNSEQCTLx
- DMA\_DNSEQCTLx
- DMA\_LL Px
- DMA\_CHCTLx

Where LLP is called a Linked-List Pointer where the value represents the next descriptor's first address in the memory. When using chained transfer, first write the register DMA\_CHCTLx.LLPEN to enable chained transfer, and write the descriptor information of the first transfer into the corresponding register. Then initialize the descriptors for subsequent transfers sequentially in memory. To end chain transfer, set DMA\_CHCTLx.LLPEN to inactive in the last descriptor, and the DMA controller will end chain transfer after transfer completion.

When the last transfer of a descriptor completes, the next descriptor specified by LLP is loaded into the channel configuration register. Wait for the next transfer request input to start the first transfer of the new descriptor. Or according to register DMA\_CHCTLx.LLPRUN settings, starting the first transfer directly after loading the new descriptor.

- When DMA\_CHCTLx.LLPRUN=0, after the last block transfer of the current descriptor, the new channel descriptor is loaded into the channel register. BTC and TC interrupts are generated as usual, and then the DMA waits for the next transfer request to start transferring the newly loaded descriptor.
- When DMA\_CHCTLx.LLPRUN=1, the transfer of the new descriptor starts immediately after loading, and neither BTC nor TC interrupt is generated for the last block transfer of the old descriptor.

Figure 16-2 Chain Transmission Diagram

### 16.3.9 NonSequence Address Transfer

Using nonSequence address transmission can realize source address and destination address to jump according to a certain offset after a certain amount of data is transmitted. Taking source address NonSequence as an example: First, set DMA\_CHCTLx.SNSEQEN to 1 to enable nonSequence address transfer. The jump direction is set forward or backward according to DMA\_CHCTLx.SINC, and then configure DMA\_SNSEQCTLx to set the specific jump mode. The control of the destination address is

similar to that of the source address, with corresponding control registers being DMA\_CHCTLx.DNSEQEN, DMA\_CHCTLx.DINC, and DMA\_DNSEQCTLx. The transfer process proceeds as shown in the following diagram.

Figure 16-3 Schematic Diagram of NonSequence Address Transfer (Taking source address as an example)

$n = SNSCNT$

$addr2 = addr1 + (n-1) \times (HSIZE/8) + SOFFSET \times (HSIZE/8)$

$addr3 = addr2 + (n-1) \times (HSIZE/8) + SOFFSET \times (HSIZE/8)$

Where HSIZE is the data width (bit), which can be 8 bits (byte), 16 bits (half-word), or 32 bits (word).

### 16.3.10 Channel Reset

The channel reset function refers to modifying the internal status register of the channel through the event request of the peripheral circuit, and reconfiguring the next data transmission mode. Set register DMA\_RCFGCTL.RCFGGEN to 1 to allow channel reset. Select the reset request source through the DMA\_RC\_TRGSEL register or trigger channel reset through software by writing to the DMA\_SWREQ.SWRCFGREQ register. When the selected reset request source input or software writing to the register generates a reset request, the channel selected by DMA\_RCFGCTL.RCFGCHS is updated according to the specified mode. The reset request only updates the internal state and does not start actual data transfer.

There are 3 ways to reset channels: linked list pointer, nonSequence, and repeated.

- When the linked list pointer reset is selected, the descriptor and internal state of the channel are all updated to the new descriptor pointed to by the linked list pointer LLP. Subsequent transfer requests are transferred according to the new descriptor.
- When selecting nonSequence or repeated reset, the channel internal state is updated as described in the following table.

Table 16-1 Channel Reset Description

| Reset Modes ( DMA_RCFGCTL) |           |           | Channel internal state                                                                          |                                                                                     |                                                                                 |
|----------------------------|-----------|-----------|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| CNTMD                      | SARMD     | DARMD     | Remaining Transfers Counter                                                                     | Source address of next transmission                                                 | Destination address of next transmission                                        |
| 0x0                        | Arbitrary | Arbitrary | Remains unchanged                                                                               | Updated based on SARMD                                                              | Updated based on DARMD                                                          |
| 0x1                        | 0x0       | Arbitrary | Remains unchanged                                                                               | Remains unchanged                                                                   | Updated based on DARMD                                                          |
|                            | 0x1       |           | Updated to the value after the next nonSequence jump in the source address in normal state      | Updated to the start address of the next source address nonSequence transfer region |                                                                                 |
|                            | 0x2, 0x3  |           | Updated to the value after the next repeated jump in the source address in normal state         | Updated to the initial setting in the DMA_SARx register                             |                                                                                 |
| 0x2, 0x3                   | Arbitrary | 0x0       | Remains unchanged                                                                               | Updated based on SARMD                                                              | Remains unchanged                                                               |
|                            |           | 0x1       | Updated to the value after the next nonSequence jump in the destination address in normal state |                                                                                     | Updated to the start address of the next destination address NonSequence region |
|                            |           | 0x2, 0x3  | Updated to the value after the next repeated jump in the destination address in normal state    |                                                                                     | Updated to the initial setting in the DMA_DARx register                         |

**Note**

When the reset function is enabled, the channel uses DMA\_RPTBx and DMA\_SNSEQCTLBx, DMA\_DNSEQCTLBx to control repeated jump and nonSequence jump of transfer addresses. Register DMA\_RPTx and DMA\_SNSEQCTLx, DMA\_DNSEQCTLx are inactive.

In the DMA action shown in the following diagram, each transfer request starts the transfer of one data block. After the first reset request, the controller skips data blocks blk1\_3 and blk1\_4, and the transfer address is updated to the starting address of the next nonSequence zone, i.e., addr2. After the second reset request occurs, the remaining number of transfers is updated to 0, that is, all data transfers are completed, the channel permission bit is automatically cleared to 0, and a transfer completion interrupt and event are generated.

Figure 16-4 Schematic Diagram of NonSequence Reset

### 16.3.11 Early Termination of Transfer

During transfer, the DMA\_CHEN.CHENx bit remains active. For non-chain transfers, the transfer count set in register DMA\_DTCTLx completes automatically and sets the bit to inactive. For chain transfers, the transfer count of the last chain transfer completes automatically and sets the bit to inactive. During transfer, if software writes 1 to DMA\_CHENCLR.CHENCLR<sub>x</sub>, DMA will terminate the transfer after completing the current data read and write, and the DMA\_CHEN.CHENx bit is cleared.

#### Notice

When software writes 1 to the CHENCLR<sub>x</sub> bit to terminate the transfer early, DMA does not save the transfer state at the time of termination. Without resetting the channel configuration register (descriptor) state and setting CHENx to 1 to re-enable the channel, DMA will retransmit the terminated data block instead of resuming from the breakpoint after a transfer request input.

### 16.3.12 Interrupt

The DMA controller can generate the following three types of interrupts:

- **Data Block Complete Interrupt DMA\_BTCx**: generated after completing a data block transfer.
- **Transmission Completion Interrupt DMA\_TCx**: generated after completing the transfer count set by DMA\_DTCTLx. CNT.
- **Transmission Error Interrupt DMA\_ERR**: when the start request overflows (that is, the channel triggers the start request again when the last request of the channel has not been responded), or when a bus error occurs during the transmission (such as accessing an illegal address or a protected address) an interrupt is generated, where in a bus error terminates the transfer immediately.

Except for the transfer request overflow error, all other interrupts can be enabled or disabled through the DMA\_CHCTLx.IE register. Additionally, all interrupts have independent MASK registers to mask the interrupts.

The above-mentioned DMA\_BTCx and DMA\_TCx interrupts can also be used as event signal outputs and can be used as trigger sources for other peripheral circuits. The event output is controlled by the MASK register but not by the DMA\_CHCTLx.IE bit. DMA\_BTCx, DMA\_TCx, and DMA\_ERR events will set the corresponding status bits in the register, regardless of the DMA\_CHCTLx.IE or MASK register settings.

## 16.4 Operation Example

### 16.4.1 Memory-to-Memory Transfer

#### Target

Transfer 12 data items from RAM address 0x20000000 to 0x20001000, with a data width of 32-bit.

#### Register Setting

1. Enable the DMA controller by writing 1 to DMA\_EN.EN.
2. Select a channel, for example channel 0, and configure the channel registers to achieve:
  - a. Write DMA\_SAR0 to configure the source address as SRAM region 0x20000000.
  - b. Write DMA\_DAR0 to configure the destination address as SRAM region 0x20001000.
  - c. Write the DMA\_DTCTL0 configuration data block size is 4, the number of transfers is 3, after each transfer one data block to produce block transfer complete interrupt, after 3 transfers complete one transfer complete interrupt
  - d. Write DMA\_RPT register configures the repeating area of the source address to be 6, that is, the original source address is reloaded after 6 addresses have been transmitted.
  - e. Configure the channel control registers DMA\_CHCTL0 to achieve:
    - 1) The source address and destination address chained transfer is disabled.
    - 2) Source address repeat enabled, destination address increment.
    - 3) The data width is 32-bit.
    - 4) Interrupt enable active.
  - f. Configure the trigger source controller DMA\_TRGSEL0 to select software trigger as the start request for DMA channel 0.
  - g. Write 1 to the channel enable bit DMA\_CHEN.CHEN0 to enable channel 0.
3. Write to the peripheral event software trigger register INTSFTTRG.STRG to 1 to send the first software start request, and DMA starts transferring data.

#### Transfer Process

Since the size of the data block is 4, the first transmission begins when INTSFTTRG.STRG is 1. When a data block transfer is completed, the transfer count DMA\_MONDTCTL0.CNT is decremented by 1, and produces a block transport complete interrupt, the software can continue to write INTSFTTRG.STRG in the interrupt subroutine to start the second transport. During the second transfer, due to the source address repeat zone size of 6, after transferring 2 addresses, the source address will reload the initial address 0x20000000, and continue to transfer the remaining 2 addresses. After the second transfer is completed, the number of transfers DMA\_MONDTCTL0.CNT is reduced by 1, and a block transfer completion interrupt is generated, and the software can continue to write INTSFTTRG.STRG in the interrupt subroutine to start the third transfer. After the third transfer is completed, the number of transfers DMA\_MONDTCTL0.CNT is reduced to 0, that is, this transfer is all completed, DMA generates

a block transfer completion interrupt and a transfer completion interrupt, and the channel enable bit DMA\_CHEN.CHEN0 will be automatically cleared.

Figure 16-5 Application Example 1: Memory-to-Memory Transfer

## 16.4.2 Memory-to-Peripheral Transfer

### Target

Transfer 10 data items of 16-bit width from RAM address 0x20000000 to the transmit buffer register of a communication module. The communication module generates a transfer request after sending each data item. After the last data item is sent, DMA generates a transfer completed interrupt.

### Register Setting

1. Enable the DMA controller by writing 1 to DMA\_EN.EN.
2. Configure DMA\_INTMSK1 to mask the block transfer completed interrupt and enable the transfer completed interrupt.
3. Select a channel, for example channel 0, and configure the channel registers to achieve:
  - a. Write DMA\_SAR0 to configure the source address as SRAM region 0x20000000.
  - b. Write DMA\_DAR0 configure destination address to register address of peripheral circuit 0x40000000.
  - c. Write DMA\_DTCTL0 configuration data block size is 1, number of transfers is 10, each transfer request is delivered once, one data at a time.
  - d. Configure the channel control registers DMA\_CHCTL0 to achieve:
    - 1) The source address and destination address chained transfer is disabled.
    - 2) Source address increment, destination address fixed.
    - 3) The source address and destination address data width is 16-bit.
    - 4) Interrupt enable active.
  - e. Configure the trigger source controller DMA\_TRGSEL0 to select the transmit buffer empty status of the communication module as the start request for DMA channel 0.
  - f. Write 1 to the channel enable bit DMA\_CHEN.CHEN0 to enable channel 0.

## Transfer Process

After the channel is enabled, DMA waits for the transmission request from the communication module. After the transmission request is generated, the DMA transmits the data in the RAM to the transmission buffer register of the communication module and waits for the second transmission request from the communication module. Because the block transmission is shielded to complete interrupt, the DMA does not generate interrupt request at this time. When all 10 data transfers are completed, DMA generates a transfer completion interrupt, and the channel enable bit DMA\_CHEN.CHEN0 will be automatically cleared.

Figure 16-6 Application Example 2: Memory-to-Peripheral Transfer

### 16.4.3 Memory-to-Memory Chain Transfer

#### Target

Perform chain transfer to transfer 3 data blocks from RAM to 3 different addresses. Where, first block: 10 data items of 32-bit width, from 0x20000000 to 0x20001000. Second block: 20 data items of 16-bit width, from 0x2000100 to 0x20001100. Third block: 40 data items of 8-bit width, from 0x20000200 to 0x20001200.

#### Register Setting

1. Enable the DMA controller by writing 1 to DMA\_EN.EN.
2. Select a channel, e.g., channel 0, and configure the first transfer descriptor (descriptor0) as follows:
  - a. Write DMA\_SAR0 to configure the source address as SRAM region 0x20000000.
  - b. Write DMA\_DAR0 to configure the destination address as SRAM region 0x20001000.
  - c. Write DMA\_DTCTL0 to configure the block size as 10.
  - d. Write the address of the second descriptor (descriptor1) 0x20002000 to the linked list pointer register DMA\_LLPO.

- e. Configure the channel control register DMA\_CHCTL0 to configure the transmission parameters for the first data block as follows:
  - 1) Chain transfer enabled.
  - 2) Chain transfer mode is to directly start the next transfer.
  - 3) Source address and destination address increment.
  - 4) The data width is 32-bit.
  - 5) Interrupt enable inactive.
3. Configure the second transfer descriptor (descriptor1) at address 0x20002000 in RAM as follows:
  - a. Write 32-bit data 0x20000100 to 0x20002000, which is the source address for the second transfer.
  - b. Write 32-bit data 0x20001100 to 0x20002004, which is the destination address for the second transfer.
  - c. Write to 0x20002008 to configure the block size as 20.
  - d. Write 32-bit data 0x20002020 to 0x20002018, which is the address of the third transfer descriptor (descriptor2).
  - e. Write to 0x2000201C the control data for the second transfer, which configures:
    - 1) Chain transfer enabled.
    - 2) Chain transfer mode is to directly start the next transfer.
    - 3) Source address and destination address increment.
    - 4) The data width is 16-bit.
    - 5) Interrupt enable inactive.
4. The descriptor for the third transfer (descriptor2) is configured in RAM at address 0x20002020, including:
  - a. Write the 32-bit data 0x20000200 to 0x20002020; this sets the source address for the third transfer.
  - b. Write the 32-bit data 0x20001200 to 0x20002024; this sets the destination address for the third transfer.
  - c. Block size as 40 at 0x20002028.
  - d. Last transfer in chain at 0x20002038 by writing 32-bit data 0x0.
  - e. Write to 0x2000203C the control data for the third transfer, which configures:
    - 1) Chain transfer disabled.
    - 2) Source address and destination address increment.
    - 3) The data width is 8-bit.
    - 4) Interrupt enable active.
5. Configure the trigger source selection register DMA\_TRGSEL0 to select software trigger as the start request for DMA channel 0.
6. Write 1 to the channel enable bit DMA\_CHEN.CHEN0 to enable channel 0.
7. Write to the software trigger register INTSFTTRG.STRG to 1 to send a start request, and DMA starts transferring data.

### Transfer Process

The software starts DMA and starts transmission. After the first transfer is completed, due to the chain transfer mode being set to directly start the next transfer and interrupts being disabled, DMA reads the second transfer descriptor (descriptor1) into the channel register. The second transfer starts directly based on the parameters configured in the descriptor. After the second transfer is completed, the third transfer descriptor (descriptor2) is read into the channel register. The third transfer starts based on the

parameters configured in the descriptor. After the third transmission is complete, the last transmission is linked according to the configuration information, and because the interrupt enable is enabled, DMA will generate a transmission finish interrupt and clear the channel enable bit DMA\_CHEN.CHEN0.

## 16.5 Register Description

### 16.5.1 Register List

- DMA1 base address: 0x40053000
- DMA2 base address: 0x40053400

Table 16-2 DMA Controller (DMA) Register Offset

| Offset      | Register                       | Description                                        | Width |

| 25:16 | DRPT[9:0] | Destination address repeat region size | Set destination address repeat area size<br>The destination device reloads the destination address to the initial setting value of the DMA_DARx register after transferring DRPT data items. Register set to 10 reloads the address after transferring 10 data items, set to 0 reloads after 1024 data items. The width of each data item is determined by DMA_CHCTLx.HSIZE. | RW     |
| 15:10 | Reserved  | Reserved                               | -                                                                                                                                                                                                                                                                                                                                                                            | -      |
| 9:0   | SRPT[9:0] | Source address repeat zone size        | Set the source address repeat area size<br>The source device reloads the source address to the initial setting value of the DMA_SARx register after transferring SRPT data items. Register set to 10 reloads the address after transferring 10 data items, set to 0 reloads after 1024 data items. The width of each data item is determined by DMA_CHCTLx.HSIZE.            | RW     |

#### Note

1. This register configures the size of the source and destination address repeat regions. Repeat transfer requires configuring the DMA\_CHCTLx.SRPTEN/DRPTEN bits to be active, and configuring the DMA\_CHCTLx.SINC/DINC bits to enable address update as increment or decrement. When configuring the DMA\_CHCTLx.SINC/DINC bits to enable address update as fixed, address repeated jump is invalid.
2. This register is disabled when the channel's reset function is enabled.

### 16.5.19 Address Repeat Control Register B (DMA\_RPTBx) (x=0-7)

Offset: 0x4C+0x40\*x

| 25:16 | DRPTB[9:0] | Destination address repeat region size | Set destination address repeat area size<br>The destination device reloads the destination address to the initial setting value of the DMA_DARx register after transferring DRPTB blocks. The block size is determined by DMA_DTCTLx.BLKSIZE and DMA_CHCTLx.HSIZE.  | RW     |
| 15:10 | Reserved   | Reserved                               | -                                                                                                                                                                                                                                                                   | -      |
| 9:0   | SRPTB[9:0] | Source address repeat zone size        | Set the source address repeat area size<br>The source device reloads the initial value set in the DMA_SARx register into the Source Address after transferring every SRPTB blocks of data. The block size is determined by DMA_DTCTLx.BLKSIZE and DMA_CHCTLx.HSIZE. | RW     |

#### Note

1. This register configures the size of the source and destination address repeat regions. Repeat transfer requires configuring the DMA\_CHCTLx.SRPTEN/DRPTEN bits to be active, and configuring the DMA\_CHCTLx.SINC/DINC bits to enable address update as increment or decrement. When configuring the DMA\_CHCTLx.SINC/DINC bits to enable address update as fixed, address repeated jump is invalid.
2. This register is only active when the channel's reset function is enabled, replacing the DMA\_RPTx register. It is disabled when the channel's reset function is disabled.

|-------|---------------|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 31:20 | SNSCNT[11:0]  | Source address jump data size | Set the amount of data transferred before the source address jumps.<br>After the source device transmits SNSCNT data, the source address jumps according to the offset specified by SOFFSET. If the register is set to 10, the address will jump after every 10 data transmissions, if it is set to 0, the address will jump after every 4096 data transmissions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | RW     |
| 19:0  | SOFFSET[19:0] | Source address jump offset    | When nonSequence address transmission, set the offset of the source address jump. The offset is relative to the current transfer address, that is, the last transfer address before the jump. The jump direction is forward or backward according to the DMA_CHCTLx.SINC bit. For details, refer to <a href="#">Schematic Diagram of NonSequence Address Transfer</a> . NonSequence address transfer is disabled when DMA_CHCTLx.SINC is set to fixed address. The jump address will be calculated according to the number of bits set by the data width (DMA_CHCTLx.HSIZE) and the value of SOFFSET.<br>Address Offset=SOFFSET×(DMA_CHCTLx.HSIZE(bit)/8)<br>For example, when SOFFSET is set to 10, and the data width is 32-bit, the address offset is 10×4=40; if the data width is 16-bit, the offset is 10×2=20; if 8-bit, the offset is 10×1=10. The next transmission's source address=current source address ± address offset | RW     |

#### Note

1. NonSequence for the source device requires configuring the DMA\_CHCTLx.SNSEQEN bit to be active, and configuring the DMA\_CHCTLx.SINC bit to enable address update as increment or decrement.
2. This register is disabled when the channel's reset function is enabled.

| 31:20 | SNSCNTB[11:0] | Source address jump data size            | Set the amount of data transferred before the source address jumps.<br>After the source device transmits SNSCNTB data blocks, the source address jumps according to the address interval specified by SNSDIST. The block size is determined by DMA_DTCTLx.BLKSIZE and DMA_CHCTLx.HSIZE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | RW     |
| 19:0  | SNSDIST[19:0] | Source nonSequence area address distance | When nonSequence address transmission, set the distance between two nonSequence areas of the source device. The jump direction is forward or backward according to the DMA_CHCTLx.SINC bit. For details, refer to <a href="#">Figure 16-4 : Schematic Diagram of NonSequence Reset</a> . NonSequence address transfer is disabled when DMA_CHCTLx.SINC is set to fixed address.<br>The address spacing is calculated based on the data width defined by the DMA_CHCTLx.HSIZE bit field and the SNSDIST value as follows:<br>Address Distance=SNSDIST×(DMA_CHCTLx.HSIZE(bit)/8)<br>For example, when SNSDIST is set to 10, and the data width is 32-bit, the address distance is 10×4=40; if 16-bit, the distance is 10×2=20; if 8-bit, the distance is 10×1=10.<br>The next transmission's source address=starting address of the current source nonSequence region ± address distance. | RW     |

#### Note

1. NonSequence for the source device requires configuring the DMA\_CHCTLx.SNSEQEN bit to be active, and configuring the DMA\_CHCTLx.SINC bit to enable address update as increment or decrement.
2. This register is only active when the channel's reset function is enabled, replacing the DMA\_SNSEQCTLx register. It is disabled when the channel's reset function is disabled.

| 31:20 | DNSCNTB[11:0] | Destination address jump data size              | Set the amount of data transferred before the destination address jumps.<br>The destination device jumps the destination address by the DNSDIST-specified distance after transferring DNSCNTB blocks. The block size is determined by DMA_DTCTLx.BLKSIZE and DMA_CHCTLx.HSIZE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | RW     |
| 19:0  | DNSDIST[19:0] | Destination nonSequence region address distance | When nonSequence address transmission, set the distance between two nonSequence areas of the destination device. The jump direction is forward or backward according to the DMA_CHCTLx.DINC bit. For details, refer to <a href="#">Figure 16-4 : Schematic Diagram of NonSequence Reset</a> . NonSequence address transfer is disabled when DMA_CHCTLx.DINC is set to fixed address.<br>The address distance is calculated based on the bit count set by the data width (DMA_CHCTLx.HSIZE) and the DNSDIST value.<br>Address Distance=DNSDIST×(DMA_CHCTLx.HSIZE(bit) /8)<br>For example, when DNSDIST is set to 10, and the data width is 32-bit, the address distance is 10×4=40; if 16-bit, the distance is 10×2=20; if 8-bit, the distance is 10×1=10.<br>The next transmission's destination address=starting address of the current destination nonSequence region ± address distance | RW     |

#### Note

1. NonSequence for the destination device requires configuring the DMA\_CHCTLx.DNSEQEN bit to be active, and configuring the DMA\_CHCTLx.DINC bit to enable address update as increment or decrement.
2. This register is only active when the channel's reset function is enabled, replacing the DMA\_DNSEQCTLx register. It is disabled when the channel's reset function is disabled.

### 16.5.24 Linked List Pointer Register (DMA\_LL Px) (x=0-7)

| Access | RO           |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | RO            |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |  |  |  |  |  |

| Bit   | Name          | Function                                | Description                                                            | Access |
|-------|---------------|-----------------------------------------|------------------------------------------------------------------------|--------|
| 31:20 | DNSCNT[11:0]  | Destination address jump data size      | Set the amount of data transferred before the destination address jump | RO     |
| 19:0  | DOFFSET[19:0] | Destination address jump address offset | Destination address offset                                             | RO     |

#### Note

The DMA\_DNSEQCTLx register remains unchanged before and after DMA transfer, while the DMA\_MONDNSEQCTLx register updates after each data block transfer by DMA.

Update method for DMA\_MONDNSEQCTLx.DNSCNT[11:0]:

- When channel reset is disabled: Subtract block size, reload initial value of DMA\_DNSEQCTLx when it is reduced to 0.
- When channel reset is enabled: Decrement by 1, reload the initial value when it reaches 0.

## 16.6 Precautions

- DMA registers only support 32-bit read and write operations, 8/16-bit read and write operations are inactive.

## 17 Voltage Comparator (CMP)

### 17.1 Introduction

Voltage Comparator (hereinafter referred to as CMP) is a peripheral module that compares two analog voltages and outputs the comparison result. This product is equipped with two groups of 4 comparison channels: CMP1 and CMP2, CMP3 and CMP4.

### 17.2 Features

- 4 comparison channels can independently perform normal comparison.
- Two comparison channels in the same group can be combined to achieve up to 2 window comparisons.
- Each comparison channel's positive and negative voltage inputs have multiple input sources (IO, PGA, DAC) to choose from.
- Hysteresis voltage is configurable.
- A noise filter can filter the comparator output, with 3 sampling clocks to choose from.
- Timer PWM can be used for comparator blanking window control.
- Interrupts can be generated at the edges of comparison result changes, other peripherals can be triggered, and STOP mode can be woken up.
- Compare results can be monitored through registers and output to the external pin VCOUT.
- Compare results can be used for EMB control events.

## 17.3 Functional Description

### 17.3.1 Function Block Diagram

Figure 17-1 CMP Function Block Diagram

Table 17-1 CMP Pin List

| Pin Name    | Input/Output | Function                     |
|-------------|--------------|------------------------------|
| AVCC        | Input        | Analog Power                 |
| AVSS        | Input        | Analog Ground                |
| CMP1_INP2   | Input        | CMP1 Positive Analog Input   |
| CMP1_INP3   | Input        | CMP1 Positive Analog Input   |
| CMP1_INP4   | Input        | CMP1 Positive Analog Input   |
| CMP123_INM3 | Input        | CMP1-3 Negative Analog Input |
| CMP1_INM4   | Input        | CMP1 Negative Analog Input   |
| CMP2_INP3   | Input        | CMP2 Positive Analog Input   |
| CMP2_INP4   | Input        | CMP2 Positive Analog Input   |
| CMP2_INM4   | Input        | CMP2 Negative Analog Input   |
| CMP3_INP2   | Input        | CMP3 Positive Analog Input   |
| CMP3_INP3   | Input        | CMP3 Positive Analog Input   |
| CMP3_INP4   | Input        | CMP3 Positive Analog Input   |
| CMP3_INM4   | Input        | CMP3 Negative Analog Input   |

| Pin Name   | Input/Output | Function                    |
|------------|--------------|-----------------------------|
| CMP4_INP3  | Input        | CMP4 Positive Analog Input  |
| CMP4_INP4  | Input        | CMP4 Positive Analog Input  |
| CMP4_INM3  | Input        | CMP4 Negative Analog Input  |
| CMP4_INM4  | Input        | CMP4 Negative Analog Input  |
| CMP1_VCOUT | Output       | CMP1 External Port Output   |
| CMP2_VCOUT | Output       | CMP2 External Port Output   |
| CMP3_VCOUT | Output       | CMP3 External Port Output   |
| CMP4_VCOUT | Output       | CMP4 External Port Output   |
| CMP_VCOUT  | Output       | CMP1-4 External Port Output |

### 17.3.2 Input Selection

The analog inputs of CMP1-4 are selected according to the following table.

Table 17-2 CMP Positive Input List

| Compare channels | CVSL=0b0001 (INP1) | CVSL=0b0010 (INP2) |           | CVSL=0b0100 (INP3) |           | CVSL=0b1000 (INP4) |
|------------------|--------------------|--------------------|-----------|--------------------|-----------|--------------------|
| CMP1             | PGA1_BP            | P2SL=0b001         | PGA1      | P3SL=0b01          | CMP1_INP3 | CMP1_INP4          |
|                  |                    | P2SL=0b010         | PGA2      | P3SL=0b10          | CMP2_INP3 |                    |
|                  |                    | P2SL=0b100         | CMP1_INP2 | -                  | -         |                    |
| CMP2             | PGA2_BP            | PGA2               |           | CMP2_INP3          |           | CMP2_INP4          |
| CMP3             | PGA3_BP            | P2SL=0b001         | PGA3      | P3SL=0b01          | CMP3_INP3 | CMP3_INP4          |
|                  |                    | P2SL=0b010         | PGA4      | P3SL=0b10          | CMP4_INP3 |                    |
|                  |                    | P2SL=0b100         | CMP3_INP2 | -                  | -         |                    |
| CMP4             | PGA4_BP            | PGA4               |           | CMP4_INP3          |           | CMP4_INP4          |

#### Note

In the table, PGA1\_BP/PGA2\_BP/PGA3\_BP/PGA4\_BP are the unamplified voltage signals output by PGA1-4, respectively. When using them, PGA should also be set to active.

Table 17-3 CMP Negative Input List

| Compare channels | RVSL=0b0001 (INM1) | RVSL=0b0010 (INM2) | RVSL=0b0100 (INM3) | RVSL=0b1000 (INM4) |
|------------------|--------------------|--------------------|--------------------|--------------------|
| CMP1             | DA1O1              | DA1O2              | CMP123_INM3        | CMP1_INM4          |
| CMP2             | DA1O1              | DA1O2              | CMP123_INM3        | CMP2_INM4          |
| CMP3             | DA2O1              | DA2O2              | CMP123_INM3        | CMP3_INM4          |
| CMP4             | DA2O1              | DA2O2              | CMP4_INM3          | CMP4_INM4          |

### 17.3.3 Normal Compare

CMP 1-4 can independently perform normal comparison. Taking CMP1 as an example, the setting steps are as follows:

**Step1.** Write 0 to PWC\_FCG3.Bit3 and wait for at least 2μs.

**Step2.** Enable CMP1 module function (PWC\_FCG3.CMP12 write 0).

- Step3.** Set CMP\_PMSR.CVSL to select the positive voltage.  
Set CMP\_PMSR.RVSL to select the negative voltage.
- Step4.** Set CMP\_MDR.CENA to 1 to enable the comparator.
- Step5.** Wait for the comparator to stabilize  $t_{CMP}$  (for specific values, see the "Electrical Characteristics" in the "Datasheet").
- Step6.** Set CMP\_FIR.FCKS to set the sampling period for digital filtering.  
Set CMP\_FIR.EDGS and CMP\_FIR.CIEN to set the edge where the interrupt occurs.
- Step7.** Set CMP\_OCR.CPOE and CMP\_OCR.COPS to set the output of VCOUT.
- Step8.** Set CMP\_OCR.COEN to 1 to allow comparator output.

**Figure 17-2 Voltage Comparison Diagram**

As shown in the figure above, during non-inverting output, if the positive voltage is higher than the negative voltage after CMP output is enabled, the CMON bit in the CMP\_MDR register is 1; if the positive voltage is lower than the negative voltage, the CMON bit is 0. During inverting output, the result of CMON is opposite to that during non-inverting output.

For CMP1 and CMP3, if INP2 or INP3 is selected as the positive voltage, then the voltage input source also needs to be selected by setting CMP\_VISR. Please see for [Table 17-2 : CMP Positive Input List](#) details.

### 17.3.4 Window Compare

Window comparison can be achieved when CMP1 and CMP2 or CMP3 and CMP4 operate simultaneously; Taking CMP1 and CMP2 as an example, the setting steps are as follows:

- Step1.** Write 0 to PWC\_FCG3.Bit3 and wait for at least 2 $\mu$ s.
- Step2.** Enable CMP1 and CMP2 module functions (PWC\_FCG3.CMP12 write 0).
- Step3.** Set CMP1\_PMSR.CVSL and select the positive terminal voltage.  
Set CMP1\_PMSR.RVSL to select the negative voltage as the lower limit of the window.
- Step4.** Set CMP2\_PMSR.CVSL to select the same positive terminal voltage as CMP1.  
Set CMP2\_PMSR.RVSL to select the negative terminal voltage as the upper limit of the window.
- Step5.** Set CMP2\_MDR.WDEN to 1 to start window comparison;
- Step6.** Set CMP1\_MDR.CENA and CMP2\_MDR.CENA to 1 to start the comparators.

- Step7.** Wait for the stabilization time  $t_{CMP}$  (refer to the "Electrical Specifications" section of the Data-sheet for specific values).
- Step8.** Set CMP2\_FIR.FCKS to set the digital filter.  
Set CMP2\_FIR.EDGS, CMP2\_FIR.CIEN to set interrupt and edge detection conditions.
- Step9.** Set CMP2\_OCR.CPOE, CMP2\_OCR.COPS to set the output of VCOOUT;
- Step10.** Set CMP1\_OCR.COEN and CMP2\_OCR.COEN to 1 to allow comparator output.

During window comparison, CMP2 completes the monitoring, filtering, interrupting, and outputting of comparison results.

**Figure 17-3 Window Compare Diagram**

As shown in the figure above, during non-inverting output, if the positive voltage is within the window composed of the two negative voltages after CMP output is enabled, the CMON bit in the CMP2\_MDR register is 1; if the positive voltage is outside the window composed of the two negative voltages, the CMON bit is 0. During inverting output, the result of CMON is opposite to that during non-inverting output.

### 17.3.5 Blank Window

The CMP can use the outputs of Timer4, Timer6, TimerA as Blank-Window signals to control the windowed output of the comparison result CMPOA, providing convenience for applications such as timer PWM zero-crossing detection.

To enable blank window output (set the CMP\_OCR.BWEN bit to 1), select one or more timer PWMs as Blank-Windows through the CMP\_BWSR.CBWS bit, and select the active level for each Blank-Window through the CMP\_BWPR.CBWP bit. In this way, when a Blank-Window is active, the window output CMPOA is fixed to the state set by the CMP\_OCR.BWOL bit.

Figure 17-4 Blank Window Output Diagram

As shown in the figure above, two PWM signals are selected as the Blank-Window, both configured as active-high. When the Blank-Window is enabled, the output state of CMPOA is forced to low level. Thus, when the Blank-Window signal is at a high level, CMPOA is forced to a low level; when Blank-Window is at a low level, CMPOA outputs the normal comparator result.

### 17.3.6 Hysteresis Function

To avoid false outputs caused by noise signals, each comparison channel has a configurable hysteresis function, and the hysteresis voltage can be selected through the CMP\_MDR.HYST bit. The hysteresis function is disabled when the HYST bit is set to 0b000.

### 17.3.7 Noise Filter

Each comparison channel contains a noise filter. The noise filter samples the comparator output CMPOA during each sampling clock period. If the same value is sampled three consecutive times, the value is output to COUT in the next sampling clock period; otherwise, COUT remains unchanged. The sampling clock can be selected through the CMP\_FIR.FCKS bit. The noise filter is disabled when the FCKS bit is set to 0b00.

### 17.3.8 External Pin Output

The comparison result COUT output by the noise filter can be output to the external port VCOU. Whether VCOU output is enabled and the output polarity (non-inverting output or inverting output) can be set through the CMP\_OCR.CPOE and COPS bits. After reset, the port corresponding to VCOU is a general-purpose port in input status. Therefore, it must also be set to VCOU output function through the port register.

### 17.3.9 Interrupt and Event

Interrupt requests can be generated for the results of all comparison channels. When using, the CMP\_FIR.CIEN bit must be set to 1, and the edge of the comparison result that can generate an interrupt is set through the CMP\_FIR.EDGS bit (value other than 0b00). If noise filtering and inverting output are used, edge detection is performed on the signal after noise filtering and inverting output.

When INTC\_WKEN.CMP\*WKEN=1, CMPO can wake up the stop low power mode. The system will be woken up and an interrupt will be generated when CMPO changes from low to high.

The generation conditions for peripheral trigger events and interrupt requests are the same, but the event trigger function must be enabled or disabled through the hardware trigger source register of the target peripheral, independent of the CIEN bit.

## 17.4 Register Description

### 17.4.1 Register List

- CMP1 base address: 0x4004A000
- CMP2 base address: 0x4004A010
- CMP3 base address: 0x4004A400
- CMP4 base address: 0x4004A410

Table 17-4 Voltage Comparator (CMP) Register Offset

| Offset | Register                 | Description                                                                | Width |
|--------|--------------------------|----------------------------------------------------------------------------|-------|

## 17.5 Precautions

### 17.5.1 Module Stop Function

CMP has a module stop function, which can turn off the digital part of the module by setting the module stop register.

CMP1 and CMP2 share a module stop control bit (PWC\_FCG3.Bit8).

CMP3 and CMP4 share a module stop control bit (PWC\_FCG3.Bit9).

All comparator channels are initially in the stopped state, and their respective registers can only be accessed when the module is set to work. Please refer to the "Action Mode and Low Power Mode" section of the "Power Control (PWC) " chapter for register settings.

### 17.5.2 Power Consumption During Module Stop

When CMP transitions from the working state to the module stop state, the comparator will continue to operate, and the power consumption is equivalent to the working state. To further reduce power consumption, please clear the CMP\_MDR.CENA bit.

### 17.5.3 Power Consumption During Stop Low Power Mode

When the chip enters stop low power mode, if CMP is in the working state, it will continue to operate after entering stop low power mode, and the power consumption is equivalent to the level before entering stop low power mode. To further reduce power consumption, please clear the CMP\_MDR.CENA bit before entering stop low power mode.

## 18 Analog-to-Digital Converter (ADC)

### 18.1 Introduction

The 12-bit ADC is an analog-to-digital converter that adopts the successive approximation method. This MCU is equipped with 3 ADC units, units 1 and 2 support 16 channels, unit 3 supports 20 channels, which can convert analog signals from external pins and inside the chip. Analog input channels can be arbitrarily combined into a sequence for single scan or continuous scan conversion. It supports continuous multiple conversions on any specified channel and averaging of the conversion results. The ADC block also includes an analog watchdog function that monitors the conversion results of any specified channel to detect if they exceed user-set ranges.

### 18.2 Features

- High Performance
  - ▶ Configurable 12-bit, 10-bit and 8-bit resolution
  - ▶ The frequency ratio of the ADC digital interface clock (PCLK4) and conversion clock (PCLK2, also known as ADCLK) can be set to 1:1, 2:1, 4:1, 8:1, 1:2, or 1:4  
PCLK2 can optionally use a PLL clock source asynchronous to the system clock (HCLK), with a frequency ratio of PCLK4:PCLK2=1:1  
PCLK2 frequency supports up to 60MHz
  - ▶ Sample Rate: 2.5Msps (PCLK2=60MHz, 12-bit, 11 sample periods, 13 conversion periods)
  - ▶ Independent programming of channel sampling time is supported
  - ▶ Each channel has an independent data register
  - ▶ Data registers can be configured for left/right alignment
  - ▶ Continuous multiple conversion averaging function
  - ▶ Oversampling function
  - ▶ Analog watchdog to monitor conversion results
  - ▶ The ADC module can be set to stop when not in use
- Analog Input Channel
  - ▶ Maximum of 28 external analog inputs, with a maximum of 20 channels supported by a single ADC unit
  - ▶ 2 internal analog signals: internal reference voltage, and VBAT divider
- Conversion Start Conditions
  - ▶ Software setup conversion started
  - ▶ Peripheral synchronously trigger the conversion to start
  - ▶ External pin trigger the conversion to start
- Conversion Mode
  - ▶ 2 scan sequences A, B, optionally specifying a single or multiple channels
  - ▶ Sequence A single scan
  - ▶ Sequence A continuous scan
  - ▶ Sequence A data buffer
  - ▶ Dual sequence scan, with sequences A and B independently selecting trigger sources, and sequence B having higher priority than A.

- ▶ Cooperative operating mode (applicable to devices with two or three ADCs)
- Interrupt and Event Signal Output
  - ▶ Sequence A scan end interrupt and event ADC\_EOCA
  - ▶ Sequence B scan end interrupt and event ADC\_EOCB
  - ▶ Analog watchdog 0 compare interrupt and event ADC\_CMP0
  - ▶ Analog watchdog 1 compare interrupt and event ADC\_CMP1
  - ▶ All the event outputs mentioned above can start DMA

## 18.3 Functional Description

### 18.3.1 Function Block Diagram

Figure 18-1 ADC Block Diagram

This chip is equipped with 3 ADC units, each with different configurations. Please refer to the table below for details:

Table 18-1 Specifications of Each ADC Unit

| Item              |     | Unit 1 (ADC1) | Unit 2 (ADC2) | Unit 2 (ADC3) |
|-------------------|-----|---------------|---------------|---------------|
| Power Supply      |     | AVCC          |               |               |
|                   |     | AVSS/VREFL    |               |               |
| Reference voltage |     | VREFH         |               |               |
| Analog Channel*1  | CH0 | ADC123_IN0    | ADC123_IN0    | ADC123_IN0    |

|                                    | On-chip peripherals | IN_TRG10                           | IN_TRG20                           | IN_TRG30                          |
|                                    |                     | IN_TRG11                           | IN_TRG21                           | IN_TRG31                          |

**Note**

In the ADC, virtual channels CH0-CH15 can be freely mapped to physical channels ADCx\_INy (actual analog input sources) through register configuration. The table shows the default mapping after reset.

### 18.3.2 ADC Clock

The ADC module requires two clocks: the digital interface clock PCLK4 and the analog circuit clock PCLK2. PCLK4 and PCLK2 are synchronized, with frequency ratios settable to 1:1, 2:1, 4:1, 8:1, 1:2, or 1:4.

PCLK2 can optionally use a PLL clock source asynchronous to HCLK, with PCLK4 and PCLK2 being the same in a synchronous and same-frequency relationship in this case.

**Notice**

PCLK2 frequency should be set within 1MHz-60MHz.

### 18.3.3 Channel Selection

The ADC block supports channel mapping, allowing virtual channels to be mapped to physical channels. Virtual channels are hypothetical channels within the ADC block. For example, setting ADC\_CHSELRA to 0x1 indicates that sequence A selects CH0 for conversion. CH0 is a virtual channel, and ADC\_DR0 is the conversion result register for virtual channel CH0. Physical channels refer to actual analog channels, including external pin analog inputs ADCx\_INy and internal analog signals such as the internal reference voltage. The mapping between virtual and physical channels can be configured through the ADC\_CHMUXR register. Refer to the register description for specifics.

**Note**

Unless otherwise specified, channel n or CHn refers to a virtual channel.

Figure 18-2 Channel Mapping Diagram

The ADC block has multiple channels configurable into two sequences: A and B. Sequences A and B have independent channel selection registers ADC\_CHSELRA and ADC\_CHSELRB. Each bit in these registers represents a channel. Writing 1 to Bit0 indicates conversion of CH0, while writing 0 indicates no conversion. Sequences A and B can independently select any one or more channels for conversion. For example, setting ADC\_CHSELRA to 0x0055 and ADC\_CHSELRB to 0x0002 means that when the trigger condition for sequence A occurs, CH0, CH2, CH4, and CH6 will be converted sequentially. When the trigger condition for sequence B occurs, CH1 will be converted.

Including, internal analog signals share CH15 with external input ADCx\_IN15. Setting ADC\_CHMUX simultaneously changes the mapping between internal analog signals/ADCx\_IN15 and CHn. To convert internal analog signals or ADCx\_IN15, first set the extended channel register ADC\_EXCHSELR, then write 1 to the corresponding virtual channel bit in ADC\_CHSELRA/B (default mapping is Bit15). When ADC\_EXCHSELR is set to 0x0, external analog input is selected. When set to 0x1, internal analog signals are selected. Selection of the 2 internal analog signals is detailed in the PWC\_PWRC4 register description in the "Power Control (PWC)" chapter.

Figure 18-3 Internal Analog Signal Selection

Additionally, most physical channels can input to multiple ADC units. For example, ADC123\_IN0 can input to ADC1, ADC2, and ADC3, while ADC12\_IN4 can input to ADC1 and ADC2. Combining the cooperative operating mode of multiple ADCs and channel mapping allows high sample rate conversion of specified channels.

**Notice**

Do not select the same channel for sequences A, B. For non-existent channels, do not set the corresponding registers and leave them in their reset state.

### 18.3.4 Trigger Source Selection

Sequences A, B independently select trigger sources. The selectable trigger sources include external ports ADCx\_ADTRG and internal events IN\_TRGx0/1. Among them, port ADCx\_ADTRG triggers are active on falling edges. IN\_TRGx0/1 are set by registers ADC\_TRGSEL0/1, which can select rich event sources inside the chip. Additionally, writing to the ADC\_STR register can generate a software trigger signal for sequence A, but can only be used when the ADC is in standby mode. Software triggers are independent of the ADC\_TRGSR register.

### 18.3.5 Sequence A Single Scan Mode

Set ADC\_CR0.MS to 0b000 to select sequence A single scan mode.

In this mode, when the trigger condition for sequence A selected by ADC\_TRGSR register occurs or ADC\_STR.STRT is written to 1 for software trigger, and then the ADC starts, sequentially sampling and converting all channels selected in ADC\_CHSELRA. Conversion results are stored in the corresponding data registers ADC\_DR. ADC\_STR.STRT remains 1 during the ADC conversion process, and is automatically cleared to 0 when all channel conversions are completed, and the ADC enters the conversion standby state, waiting for the next trigger condition to occur.

When all channel conversion ends, the sequence A conversion end flag bit ADC\_ISR.EOCAP is set to 1 and the sequence A conversion end event ADC\_EOCA is generated, which can be used to start the DMA. If the ADC\_ICR.EOCAIEN is 1, the sequence A conversion end interrupt request is generated in the state of interrupt enable.

Figure 18-4 Sequence A Single Scan Mode

Software flow for sequence A single scan mode:

- Step1.** Confirm ADC\_STR.STRT is 0, placing the ADC in conversion standby mode;
- Step2.** Set ADC\_CR0.MS to 0b000 to select sequence A one-shot scan mode;
- Step3.** Set sequence A channel selection register ADC\_CHSELRA;
- Step4.** Set the sampling time register ADC\_SSTR;
- Step5.** Write 1 to ADC\_STR.STRT for software trigger of sequence A or set ADC\_TRGSR to select the trigger condition for sequence A;
- Step6.** Poll the sequence A conversion end flag bit EOCAF;
- Step7.** Read the channel data registers ADC\_DR;
- Step8.** Write 0 to clear the EOCAF flag bit, preparing for the next conversion.

The CPU query modes in steps 6-8 above can also be replaced by interrupt mode, use the ADC\_EOCA interrupt to handle the converted data. Or start DMA read data using the ADC\_EOCA event.

### 18.3.6 Sequence A Continuous Scan Mode

Set ADC\_CR0.MS to 0b001 to select sequence A continuous scan mode.

Sequence A continuous scan mode is similar to single scan mode, but after all channels are converted, conversion sequence A is restarted instead of entering standby mode. STRT bits also do not automatically clear 0.

Write 0 to the STRT bit and read STRT to confirm 0 to determine that the ADC enters the conversion standby state when a continuous scan needs to be stopped.

Figure 18-5 Continuous Scan

Software flow for sequence A continuous scan mode:

- Step1.** Confirm ADC\_STR.STRT is 0, placing the ADC in conversion standby mode;

- Step2.** Set ADC\_CR0.MS to 0b001 to select sequence A continuous scan mode;
- Step3.** Set sequence A channel selection register ADC\_CHSELRA;
- Step4.** Set the sampling time register ADC\_SSTR;
- Step5.** Write 1 to ADC\_STR.STRT for software trigger of sequence A or set ADC\_TRGSR to select the trigger condition for sequence A;
- Step6.** Poll the sequence A conversion end flag bit EOCAF;
- Step7.** Read the channel data registers ADC\_DR;
- Step8.** Write 0 to clear the EOCAF flag for preparation of the next conversion.
- Step9.** Write 0 to the STRT bit when you do not need to continue the conversion, and read STRT to confirm 0 to determine the ADC is in conversion standby.

The query modes in steps 6-8 can be replaced with interrupt handling, use the ADC\_EOCA interrupt to handle the converted data. Or start DMA read data using the ADC\_EOCA event.

#### Notice

Because it is a continuous conversion, the interval between each scan is relatively short, especially when only one channel is selected for conversion. It is recommended to use the ADC\_EOCA event to start DMA read data in order to avoid data loss due to intinelly processing in query mode.

### 18.3.7 Sequence A Data Buffer Mode

Set ADC\_CR0.MS to 0b100 to select data buffer mode for sequence A.

The sequence A data buffer mode is similar in action to the sequence A single scan mode. The difference lies in that after the conversion of one channel in the data buffer mode is completed, it does not directly start the conversion of the next channel, but enters the conversion standby state and does not start the conversion of the next channel until the startup condition occurs again.

When all channel conversion ends, the sequence A conversion end flag bit ADC\_ISR.EOCAF is set to 1 and the sequence A conversion end event ADC\_EOCA is generated, which can be used to start the DMA. If the ADC\_ICR.EOCAIEN is 1, the sequence A conversion end interrupt request is generated in the state of interrupt enable.

This mode allows multiple virtual channels selected in ADC\_CHSELRA to be mapped to the same physical channel using channel mapping. After all channels are converted, conversion data can be read sequentially from the corresponding ADC\_DR registers.

Figure 18-6 Data Buffer Mode

Software flow for sequence A data buffer mode:

- Step1.** Confirm ADC\_STR.STRT is 0, placing the ADC in standby mode;

- Step2.** Set ADC\_CR0.MS to 0b100 to select sequence A data buffer mode;
- Step3.** Set sequence A channel selection register ADC\_CHSELRA;
- Step4.** Set the channel mapping control register ADC\_CHMUXR;
- Step5.** Set the sampling time register ADC\_SSTR;
- Step6.** Write 1 to ADC\_STR.STRT for software trigger of sequence A or set ADC\_TRGSR to select the trigger condition for sequence A;
- Step7.** Poll for single conversion end ADC\_STR.STRT=0;
- Step8.** Repeat steps 6-7 until all channels are converted;
- Step9.** Poll the sequence A conversion end flag bit EOCAF;
- Step10.** Read the channel data registers ADC\_DR;
- Step11.** Write 0 to clear the EOCAF flag bit, preparing for the next conversion.
- Steps 9-11 can be replaced with interrupt handling, use the ADC\_EOCA interrupt to handle the converted data. Or start DMA read data using the ADC\_EOCA event.

### 18.3.8 Dual Sequence Scan Mode

Set ADC\_CR0.MS to 0b010 or 0b011 to select dual sequence scan mode, allowing both sequences A and B to be started by their respective trigger conditions.

When MS=0b010, sequences A and B are equivalent to two independent single scan sequences. MS=0b011, sequence A is continuous scan mode, sequence B is single scan mode. MS=0b110, sequence A is data buffer mode, B is single scan mode.

Sequence A is triggered by ADC\_TRGSR.TRGSELA and selects channels with ADC\_CHSELRA. Sequence B is triggered by ADC\_TRGSR.TRGSELB and selects channels with ADC\_CHSELRB.

When the conversion of all channels in sequence A is completed, the sequence A conversion end flag bit ADC\_ISR.EOCAF is set to 1 and the sequence A conversion end event ADC\_EOCA is generated. If the sequence A conversion end flag bit ADC\_ISR.EOCAIEN is set to 1, the sequence A conversion end interrupt request is generated in the state of interrupted permission. When the conversion of all channels of sequence B ends, the sequence B conversion end flag ADC\_ISR.EOCBF is set to 1, and the sequence B conversion end event ADC\_EOCB is generated. If ADC\_ISR.EOCBIEN is 1, the interrupt is enabled and the sequence B conversion end interrupt is generated at the same time.

In dual sequence scanning mode, sequence B will be prioritized when sequence A is competing with sequence B, that is, sequence B has higher priority than sequence A. Please refer to the table below for details.

Table 18-2 Various Conflicts Between Sequences A and B

| ADC Conversion               | Trigger Signal Occurrence | Mode of Treatment                                                                                                                                              |                                                                                                                                                         |
|------------------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |                           | ADC_CR1.RSCHSEL=0                                                                                                                                              | ADC_CR1.RSCHSEL=1                                                                                                                                       |
| During Sequence A Conversion | Sequence A Triggering     | Inactive trigger signal                                                                                                                                        |                                                                                                                                                         |
|                              | Sequence B Triggering     | 1. Sequence A conversion interrupted, sequence B conversion started<br>2. After Sequence B conversion completes, sequence A continues from interrupted channel | 1. Sequence A conversion interrupted, sequence B conversion started<br>2. After Sequence B conversion completes, sequence A restarts from first channel |

|                                                           | Sequence B Triggering     | Inactive trigger signal                                                                                 |                   |
| In AD idle, sequence A and B are triggered simultaneously |                           | Sequence B starts first, after all channel conversions are complete, sequence A conversions are started |                   |

Figure 18-7 Dual Sequence Scan Mode (Sequence A Restarts from Interrupted Channel)

Figure 18-8 Dual Sequence Scan Mode (Sequence A Restarts from First Channel)

Software flow for dual sequence scan mode:

**Step1.** Confirm ADC\_STR.STRT is 0, placing the ADC in standby mode;

- Step2.** Set ADC\_CR0.MS to 0b010 or 0b011 to select dual sequence scan mode;
- Step3.** Set ADC\_CR1.RSCHSEL register to select the startup method after Sequence A is interrupted;
- Step4.** Set sequence A channel selection register ADC\_CHSELRA;
- Step5.** Set sequence B channel selection register ADC\_CHSELRB;
- Step6.** Set the sampling time register ADC\_SSTR;
- Step7.** Set ADC\_TRGSR register to select trigger conditions for Sequence A and B;
- Step8.** Handle conversion data after Sequence A or B conversion ends by polling EOCAF, EOCBF, using ADC\_EOCA, ADC\_EOCB interrupts, or initiating DMA.

**Notice**

Do not select the same channel for sequences A and B. Do not select the same trigger source for sequences A and B.

### 18.3.9 Analog Watchdog Function

The analog watchdog function refers to comparing the conversion result at the end of an ADC conversion for a channel. This ADC supports two comparison windows: window 0 and window 1. Taking window 0 as an example, as shown in the figure below, if the conversion result is within the protected area, a watchdog comparison interrupt and event ADC\_CMP0 are generated.

Figure 18-9 Analog Watchdog Protected Area (Comparative Mode)

Software flow for using the analog watchdog function (Taking window 0 as an example) :

- Step1.** Set the threshold registers AD\_AWD0DR0 and ADC\_AWD0DR1;
- Step2.** Set the comparison channel register (ADC\_AWD0CHSR) to select the channels to be compared;
- Step3.** Set ADC\_AWDCR.AWD0MD to select the comparative mode;
- Step4.** Set ADC\_AWDCR.AWD0IEN interrupt permission bit;
- Step5.** Set ADC\_AWDCR.AWD0EN to enable the watchdog window 0 comparison function;
- Step6.** Set the scan mode according to the previous steps and start the ADC conversion;
- Step7.** In the ADC\_CMP0 interrupt or after ADC conversion ends, query the comparison status register (ADC\_AWDSR.AWD0F) and process the comparison result accordingly.

The usage of comparison window 1 is the same as window 0.

Two comparison windows can be used in combination. When the window combination function is enabled, at the end of the conversion for the channel selected in window 1, the comparison interrupt ADC\_CMP1 outputs not just the comparison result from window 1 alone, but a combined result of logical OR, AND, or XOR of the comparison results from windows 0 and 1, as set.

The software flow for using the window combination comparison function is similar to using the windows individually. After setting up windows 0 and 1, additionally set the ADC\_AWDCR.AWDCM register to select the combination method.

### 18.3.10 Sampling Time and Conversion Time for Analog Inputs

In single scan mode, ADC conversion can be started by software settings, internal triggers IN\_TRGx0/1, and external pin triggers ADCx\_ADTRG startup mode. After the scan conversion delay time  $t_D$ , the ADC module starts to sample and convert the analog channel. After all the conversions are completed, the conversion end delay time  $t_{ED}$  enters the standby state, and a scan is finally completed. The continuous scanning mode is similar to a single scanning mode, except that there is no  $t_D$  time at the second time of the sequence and at the start of the sequence.

The conversion time of a single channel is  $t_{CONV} = t_{SPL} + t_{CMP}$ . Among them,  $t_{SPL}$  represents the sampling time of the analog input, and the number of sampling periods can be adjusted according to the input impedance setting register ADC\_SSTR.  $t_{CMP}$  represents the successive comparison time, with 13 PCLK2 for 12-bit precision, 11 PCLK2 for 10-bit precision, and 9 PCLK2 for 8-bit precision.

The time of one scan conversion  $t_{SCAN} = t_D + \sum t_{CONV} + t_{ED}$ . Among them,  $\sum t_{CONV}$  represents the sum of the conversion time of all scanning channels. Since the sampling time  $t_{SPL}$  can be set independently, the conversion time  $t_{CONV}$  of each channel can be different.

Figure 18-10 ADC Conversion Time Diagram

Table 18-3 ADC Conversion Time

| Name              |                   | Description                         |                                                                | Conditions                     |                                                |                      |                  |
|-------------------|-------------------|-------------------------------------|----------------------------------------------------------------|--------------------------------|------------------------------------------------|----------------------|------------------|
|                   |                   |                                     |                                                                | Synchronous Peripheral Trigger | Asynchronous Peripheral Trigger <sup>(1)</sup> | External Pin Trigger | Software Trigger |
| t <sub>D</sub>    |                   | Scan start processing time          | ADC is idle, start conversion                                  | 4 PCLK2                        | 3 PCLK4 + 4 PCLK2 + 1 PCLK4_SYNC               | 2 PCLK4 + 4 PCLK2    | 3 PCLK2          |
|                   |                   |                                     | Sequence A conversion interrupted, start sequence B conversion | 5 PCLK2                        | 4 PCLK4 + 5 PCLK2 + 1 PCLK4_SYNC               | 2 PCLK4 + 5 PCLK2    | -                |
| t <sub>CONV</sub> | t <sub>SPL</sub>  | Sample time                         |                                                                | ADC_SSTRx.SST x PCLK2          |                                                |                      |                  |
|                   |                   | Successive conversion time          | 12-bit resolution                                              | 13 PCLK2                       |                                                |                      |                  |
|                   | 10-bit resolution |                                     | 11 PCLK2                                                       |                                |                                                |                      |                  |
|                   | 8-bit resolution  |                                     | 9 PCLK2                                                        |                                |                                                |                      |                  |
| t <sub>ED</sub>   |                   | Scan completion processing time     |                                                                | 3 PCLK2                        |                                                |                      |                  |
| t <sub>TD</sub>   |                   | Minimum continuous trigger interval |                                                                | Σt <sub>CONV</sub> + 6 PCLK2   |                                                |                      |                  |

**Note**

1. Asynchronous peripheral trigger refers to the situation where the ADC block selects a PLL clock that is asynchronous to the system clock for operation. At this time, the peripheral module clock and the ADC module clock are in an asynchronous relationship. PCLK4\_SYNC represents the original synchronization clock of the ADC block (i.e., the clock set by CMU\_SCFGR), where PCLK4 and PCLK2 are the same and are both asynchronous PLL clocks.

### 18.3.11 ADC Data Register Automatic Clear Function

When ADC\_CR0.CLREN is 1, the ADC\_DR register will be automatically cleared to 0x0000 after being read by the CPU or DMA.

Using this function allows detection of whether the ADC\_DR register has been updated. Examples are provided below.

- When ADC\_CR0.CLREN is 0, automatic clear function disabled, if the analog quantity to be measured (0x0222) is not converted for some reason or the result is not updated to the ADC\_DR register, the ADC\_DR register will continue to hold the previous conversion value (0x0111). During ADC conversion completion interrupt handling, the not updated value (0x0111) will be read. To detect whether the ADC conversion value is enabled, it is necessary to additionally store the previous conversion value in RAM and judge by comparing the conversion results.
- When ADC\_CR0.CLREN is 1, automatic clear function enabled, after the previous conversion result (0x0111) is read by the CPU or DMA, the ADC\_DR register will be automatically cleared to 0x0000. After subsequent ADC conversions, if the conversion result is not correctly transferred to the ADC\_DR register, the ADC\_DR register will remain at 0x0000. In this case, if 0x0000 is read during interrupt handling, it is easy to determine whether the ADC conversion data has been stored correctly.

### 18.3.12 Conversion Data Averaging Function

The ADC conversion averaging function refers to performing 2, 4, 8, 16, 32, 64, 128, or 256 consecutive conversions on the same channel and averaging the conversion results before storing them in the data register. Using the averaging function can remove certain noise components and make the conversion results more precise.

The register ADC\_CR0.AVCNT sets the number of consecutive conversions, and the register ADC\_AVCHSELR selects any one or more channels to be averaged.

Figure 18-11 Conversion Action When Averaging Function is Enabled

In the diagram above, in sequence A single scan mode, 4 channels CH0-3 are selected for conversion, with CH1 and CH2 set to twice averaging mode. During the scanning process, CH1 and 2 will perform

two consecutive conversions, and save the averaged results to the data registers ADC\_DR1 and 2 of the corresponding channel.

### 18.3.13 Oversampling

By setting ADC\_CR2.OVSMOD to 1 and selecting any one or more channels for oversampling through setting ADC\_AVCHSELR, the AD enters oversampling mode. In this mode, multiple consecutive sampling conversions and result shifting are performed to obtain a 16-bit precision conversion result. The final conversion result is calculated using the following formula:

$$\text{AD oversampling result} = \frac{1}{2^M} \times \sum_{n=1}^{n=N} \text{AD conversion result of the } n\text{th time}$$

The sample rate N is set through ADC\_CR0.AVCNT and can be set to 2 to 256 samples.

The divisor series M is set through ADC\_CR2.OVSS and can be set to shift right by up to 8 bits.

### 18.3.14 Programmable Gain Amplifier PGA

This product is equipped with a Programmable Gain Amplifier PGA. The register ADC\_PGACR can be set to enable the PGA circuit and select the gain multiplier, with a gain range of x2-x32. In this case, the analog input is first amplified by the PGA circuit before being input to the ADC module for conversion.

Before using the PGA, please set bit3 of the register PWC\_FCG3 to enable the PGA and wait for a startup stabilization time of 2μs.

Figure 18-12 PGA and SH Channel Diagram for ADC1 and ADC2

As shown in the diagram above, ADC1 contains 3 PGA channels PGA1-3, which correspond to physical channels ADC123\_IN0-2, respectively. ADC2 contains 1 PGA channel PGA4, which corresponds to physical channel ADC12\_IN6.

The reference ground for the PGA can be selected as either internal AVSS or external PGAx\_VSS. When selecting external PGAx\_VSS, please connect it to the same voltage as AVSS.

### 18.3.15 Dedicated Sample Hold Circuit (SH) for Channels

This product is equipped with 3 dedicated sample hold circuits (SH) for use by channels CH0-2 of ADC1. When the dedicated sample hold circuit is enabled, at the start of each sequence, all channels with SH enabled are sampled simultaneously, then the ADC is triggered to perform conversion on each channel in the sequence one by one. In continuous scanning mode, the sampling time of SH will be inserted into the sequence at the start of the second and subsequent scanning.

The ADC\_SHCR.SHSEL bit can be set to enable the SH circuit, and the ADC\_SHCR.SHSST bit can be set to modify the sample period count of the SH circuit.

Before using SH, please set Bit3 of the PWC\_FCG3 register to enable SH and wait for a startup stabilization time of 2μs.

As shown in the diagram below, ADC1 contains 3 SH circuits, which can be used in combination with PGA. That is, it is first amplified by PGA, then sampled and held by SH, and finally input to the ADC for conversion. Alternatively, the PGA can be disabled, and the external pin input can be directly sampled by SH and then input to the ADC for conversion.

Figure 18-13 Dedicated Sample Hold Circuit for Channels Enabled

As shown in the diagram above, the dedicated sample hold circuits SH1-3 for CH0-2 are all enabled. After the sequence start trigger, the SH1-3 circuits pre-sample the analog inputs of channels CH0-2 simultaneously, which is represented by the time  $t_{SHSLP}$  in the diagram. Then, the ADC converts the analog voltages held by SH1-3. Where,  $t_{SHSLP} = t_{SH} + t_{SHW}$ .  $t_{SH}$  represents the sampling time of the dedicated sample hold circuit, which is set by ADC\_SHCR.SHSST and should be set to above  $0.4\mu s$ .  $t_{SHW}$  represents the waiting time after the sampling hold circuit completes sampling, which is 12 PCLK2 periods.

#### Notice

- In dual sequence scan mode, do not use SH in sequence A. This is because sequence A may be interrupted by sequence B, resulting in inconsistent sampling times for each dedicated sample hold circuit and unexpected conversion results.
- After writing 1 to ADC\_SHCR.SHSEL, the SH circuit is enabled, and the corresponding virtual channels CH0-2 are fixedly mapped to physical channels ADC123\_IN0-2. That is, when the SH circuit is enabled, the corresponding virtual channels do not support channel mapping.

### 18.3.16 Multi-ADC Cooperative Working Mode

On chips equipped with 2 or 3 ADC units, the ADC cooperative working mode can be used.

In the ADC cooperative working mode, ADC1 acts as the master unit, and the conversion of ADC2 and ADC3 is synchronized through the trigger signal of ADC1. That is, the setting of ADC\_TRGSR.TRGSELA for sequence A of ADC2 and ADC3 is invalid. All ADC units are triggered by the trigger source selected by the trigger source selection register for sequence A of ADC1. In this mode, writing 1 to ADC\_STR.STRT does not start the conversion, i.e., software start is disabled.

When using the cooperative working mode, please prohibit the sequence B action, so as not to disturb the synchronization. Two ADC units, ADC1 and ADC2, can be set to work cooperatively, or ADC1, ADC2, and ADC3 three ADC units can be set to work cooperatively.

The ADC can be configured into the following four cooperative working modes:

- [Single Parallel Trigger Mode](#)
- [Single Delay Trigger Mode](#)
- [Loop Parallel Trigger Mode](#)

## ● Loop Delay Trigger Mode

### Single Parallel Trigger Mode

The trigger condition of sequence A of ADC1 simultaneously triggers all ADC units in cooperative working mode, and only triggers once.

Figure 18-14 Single Parallel Trigger Mode (Three ADCs)

#### Notice

Disable multiple ADCs from simultaneously converting the same analog input. One analog channel can only be sampled by one ADC unit at a time; otherwise, the accuracy is not guaranteed. The same applies below.

Software setup flow for this mode:

- Step1.** Write 0 to the collaborative work permission register `ADC_SYNCRR.SYNCEN` to confirm that the collaborative work is disabled.
- Step2.** Set ADC1 unit:
- Confirm that `ADC1_STR.STRT` is 0, and ADC1 is in conversion standby mode.
  - Set the control register `ADC1_CR0.MS` to 0b000 (Sequence A single scan mode) or 0b001 (Sequence A continuous scan mode).
  - Set sequence A channel selection register `ADC1_CHSELRA`.
  - Set the sampling time register `ADC1_SSTR`.
  - Set the sequence A trigger source selection register `ADC1_TRGSR`.
- Step3.** Set ADC2 unit:
- Confirm that `ADC2_STR.STRT` is 0, and ADC2 is in conversion standby mode.
  - Set the control register `ADC2_CR0.MS`, channel selection register `ADC2_CHSELRA`, and channel sampling time register `ADC2_SSTR`.

#### Note

To ensure synchronous operation of ADC2 and ADC1, the above registers should be set to the same values as those of ADC1 as much as possible. The specific channels do not need to be the same, as long as the number of channels and the sampling time of the corresponding channels are consistent.

- Step4.** Set the ADC3 unit (For three ADCs working cooperatively).
- Confirm that `ADC3_STR.STRT` is 0, and ADC3 is in conversion standby mode.

- b. Set the control register ADC3\_CR0.MS, channel selection register ADC3\_CHSELRA, and channel sampling time register ADC3\_SSTR.

**Note**

Same as ADC2, to ensure synchronous operation between ADC3 and ADC1, the above registers should preferably be configured with the same values as ADC1's registers.

- Step5.** Set the cooperative mode control register ADC\_SYNCCR.SYNCMD to 0b010 (Cooperative working of ADC1 and ADC2) or 0b011 (Cooperative working of ADC1, ADC2, and ADC3).
- Step6.** Write 1 to the cooperative work enable register ADC\_SYNCCR.SYNCEN to enable cooperative working.
- Step7.** Wait for the input of the trigger source for sequence A of ADC1, and process the results after ADC1, ADC2, and ADC3 complete the conversion.

### Single Delay Trigger Mode

The trigger condition of sequence A of ADC1 triggers ADC1, and after a set delay, triggers ADC2 to start conversion, and then after another set delay, triggers ADC3 to start conversion. Each ADC unit is triggered only once.

Figure 18-15 Single Delay Trigger Mode (Three ADCs)

**Notice**

- After the first input of the sequence A trigger of ADC1, before the cooperative trigger of ADC3 occurs, any subsequent input of the sequence A trigger of ADC1 will be ignored.
- If each ADC unit converts the same analog channel, the sampling time needs to be staggered, that is, the delay time  $t_{SYNCDLY}$  and the channel opening sampling time  $t_{SPL}$  need to satisfy:  $t_{SYNCDLY} > t_{SPL}$ .

Software setup flow for this mode:

- Step1.** Write 0 to the cooperative work enable register ADC\_SYNCCR.SYNCEN to disable cooperative working.
- Step2.** Set ADC1, ADC2, and ADC3 units (refer to single parallel mode).
- Step3.** Set the cooperative mode control register ADC\_SYNCCR.SYNCDLY to set the start delay for the two ADCs.

- Step4.** Set the cooperative mode control register ADC\_SYNCRR.SYNCMD to 0b000 (Cooperative working of ADC1 and ADC2) or 0b001 (Cooperative working of ADC1, ADC2, and ADC3).
- Step5.** Write 1 to the cooperative work enable register ADC\_SYNCRR.SYNCEN to enable cooperative working.
- Step6.** Wait for the input of the trigger source for sequence A of ADC1, and process the results after ADC1, ADC2, and ADC3 complete the conversion.

### Loop Parallel Trigger Mode

The trigger condition of sequence A of ADC1 simultaneously triggers all ADC units in cooperative working mode, and then after a specified delay, triggers all ADC units again simultaneously. This continues until the ADC1 unit is manually stopped by software or the cooperative working mode is disabled.

Figure 18-16 Loop Parallel Trigger Mode (Three ADCs)

#### Notice

The delay time  $t_{SYNCDLY}$  and the time  $t_{SCAN}$  of a scan conversion need to satisfy:  $t_{SYNCDLY} > t_{SCAN}$ .

The software setting process of this mode is as follows:

- Step1.** Write 0 to the cooperative work enable register ADC\_SYNCRR.SYNCEN to disable cooperative working.
- Step2.** Set ADC1, ADC2, and ADC3 units (refer to single parallel mode). Set ADC\_CR0.MS to 0b000 (refer to sequence A single scan mode).
- Step3.** Set the cooperative mode control register ADC\_SYNCRR.SYNCDLY to set the delay for each parallel trigger.
- Step4.** Set the cooperative mode control register ADC\_SYNCRR.SYNCMD, write 0b110 (Cooperative working of ADC1 and ADC2) or write 0b111 (Cooperative working of ADC1, ADC2, and ADC3).
- Step5.** Write 1 to the cooperative operation enable register ADC\_SYNCRR.SYNCEN to enable cooperative working.
- Step6.** Wait for the input of the trigger source for sequence A of ADC1, and process the results after ADC1, ADC2, and ADC3 complete the conversion.

## Loop Delay Trigger Mode

After the trigger condition of sequence A of ADC1 triggers ADC1, after a set delay, it sequentially and cyclically triggers ADC2, ADC3, ADC1, ADC2, etc., until the ADC1 unit is manually stopped by software or the cooperative working mode is disabled.

Figure 18-17 Loop Delay Trigger Mode (Two ADCs)

Figure 18-18 Loop Delay Trigger Mode (Three ADCs)

### Notice

When the two ADCs cooperative working, The delay time  $t_{SYNCDLY}$  and the time  $T_{SCAN}$  of a scan conversion need to satisfy:  $t_{SYNCDLY} > t_{SCAN}/2$ . When the three ADCs cooperative working, it needs to satisfy:  $t_{SYNCDLY} > t_{SCAN}/3$ . At the same time, if ADC1, ADC2, and ADC3 convert the same analog channel, the sampling time needs to be staggered, that is,  $t_{SYNCDLY} > t_{SPL}$ .

Software setup flow for this mode:

- Step1.** Write 0 to the cooperative work enable register `ADC_SYNCRR.SYNCCEN` to disable cooperative working.
- Step2.** Set ADC1, ADC2, and ADC3 units (refer to loop parallel trigger mode).
- Step3.** Set the cooperative mode control register `ADC_SYNCRR.SYNCDLY` to set the delay for each trigger.

- Step4.** Set the cooperative mode control register ADC\_SYNCCR.SYNCMD to 0b100 (Cooperative working of ADC1 and ADC2) or 0b101 (Cooperative working of ADC1, ADC2, and ADC3).
- Step5.** Write 1 to the cooperative operation enable register ADC\_SYNCCR.SYNCEN to enable cooperative working.
- Step6.** Wait for the input of the trigger source for sequence A of ADC1, and process the results after ADC1, ADC2, and ADC3 complete the conversion.

### 18.3.17 Interrupt and Events

The ADC block can generate the following kinds of event outputs. When each event occurs, if the corresponding interrupt enable register is set to active, an interrupt request is simultaneously output.

- For sequence A scan end ADC\_EOCA, corresponding to interrupt enable register ADC\_ICR.EOCAIEN
- For sequence B scan end ADC\_EOCB, corresponding to interrupt enable register ADC\_ICR.EOCBIEN
- For analog watchdog window 0 compare ADC\_CMP0, corresponding interrupt enable register ADC\_AWDCR.AWD0IEN
- For analog watchdog window 1 compare ADC\_CMP1, corresponding interrupt enable register ADC\_AWDCR.AWD1IEN

The above all event outputs can initiate other on-chip peripheral modules, including starting DMA transfer. Using DMA transfer allows continuous reading of ADC conversion results without software intervention, fully implemented by hardware, reducing CPU load. DMA settings are described in the relevant sections of the "DMA Controller (DMA) " chapter. Event signal output is independent of the interrupt enable bit control, and will be output as long as the condition occurs.

Figure 18-19 ADC Interrupt and Event Output Timing

## 18.4 Register Description

### 18.4.1 Register List

- ADC1 base address: 0x40040000
- ADC2 base address: 0x40040400
- ADC3 base address: 0x40040800

Table 18-4 Analog-to-Digital Converter (ADC) Register Offset

| Offset     | Register     | Description                                                                                                                                                                 | Width |
|------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| 0x00       | ADC_STR      | Start Register                                                                                                                                                              | 8     |
