In order to avoid subsequent synchronization failures causing by the inconsistent scanning time <math>t_{SCAN}</math> of each ADC.<br/>           When the software writes 0 to ADC1_STR.STRT to force the conversion to stop, SYNCEN is automatically cleared to 0.         </div> | RW     |

### 18.4.17 ADC Data Register (ADC\_DRx)

This register is a read-only register used to store the ADC conversion data for each channel. The storage method of conversion result data varies depending on the oversampling mode, data alignment, and conversion resolution.

Offset:  $0x50 + 0x2 \times x$  ("x" represents the channel. For ADC1 and ADC2,  $x=0-15$ ; for ADC3,  $x=0-19$ )

#### Oversampling Mode

| Offset | Bit Position |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| 10:8  | SHSEL    | Dedicated Sample Hold Circuit Channel Selection | Corresponding to SH3-SH1: <ul style="list-style-type: none"> <li>● 0b0: Bypass the dedicated sample hold circuit</li> <li>● 0b1: Enable the dedicated sample hold circuit</li> </ul> <div> <b>Note</b><br/>           Each bit corresponds to one channel.<br/><br/>           In dual sequence scan mode, do not use the dedicated sample hold circuit in sequence A. This is because sequence A may be interrupted by sequence B, resulting in unexpected conversion results by the inconsistent sampling times for each dedicated sample hold circuit.         </div> | RW     |
| 7:0   | SHSST    | Sample Time Selection                           | <ul style="list-style-type: none"> <li>● 0x00-0x03: Setting prohibited</li> <li>● 0x04: PCLK2 Clock Cycle×4</li> <li>● .....</li> <li>● 0xFF: PCLK2 Clock Cycle×255</li> </ul> <div> <b>Note</b><br/>           When PCLK2 operates at 50MHz, one period is 20ns. The initial period setting is 24 periods. When the input impedance is high, resulting in insufficient sample time, or when the PCLK2 frequency is low, the sample time can be adjusted. The sample time should not be less than 0.4μs.         </div>                                                  | RW     |

### 18.4.24 Programmable Gain Amplifier Control Register (ADC\_PGACRx) (x=1-3)

#### Note

- Unit 1 (ADC1) supports 3 channels for PGA1-3. Please refer to [Mapping Relationship with Physical Channels](#). The ADC1\_PGACR1-3 registers correspond to the control of PGA1-3, respectively.
- Unit 2 (ADC2) supports 1 channel for PGA4. Please refer to [Mapping Relationship with Physical Channels](#). The ADC2\_PGACR1 register corresponds to the control of PGA4.
- Unit 3 (ADC3) does not support PGA.

### 18.4.25 Programmable Gain Amplifier Reference Ground Selection Register (ADC\_PGAVSS-SENr)

**Note**

- Units 1 (ADC1) and 2 (ADC2) support PGA.
- Unit 3 (ADC3) does not support PGA.

| Offset | Bit Position |   |   |   |   |           |   |   |

## 18.5 Precautions

### 18.5.1 Precautions for Reading Data Registers

Please access the ADC data registers (ADC\_DR) in half-word units. Do not access data registers in byte units.

### 18.5.2 Precautions for Handling Scan Completion Interrupts

When two consecutive scan conversions are performed on the same channel, during the period from the completion of interrupt handling in the first conversion to the completion of interrupt handling in the second conversion, if the CPU does not read the first converted data in time, the second converted data will overwrite the first converted data.

### 18.5.3 Precautions for Module Stop and Low Power Settings

The ADC module can be stopped and power consumption reduced by setting the PWC\_FCG register. The ADC is initially in the stopped state. To start the ADC module, first set the corresponding bit in the PWC\_FCG register to cancel the stop, and wait for 1 $\mu$ s before starting the ADC conversion.

Before setting the module to stop, please confirm that the ADC is in the conversion stop state, i.e., the ADC\_STR.STRT bit is 0.

Before setting the system to enter STOP mode, please set the ADC to module Stop mode first.

For specific descriptions, please refer to the relevant sections of the "Action Mode and Low Power Mode" section in the "Power Control (PWC) " chapter.

### 18.5.4 ADC Conversion Analog Channel Input Pin Settings

When setting a chip pin as an ADC analog channel input, please first disable the digital function (PCRxy.DDIS) of the corresponding pin. For specific descriptions, please refer to the "General-Purpose I/O (GPIO)" chapter.

### 18.5.5 Noise Control

To prevent abnormal voltages such as surges from damaging the analog input pin, it is recommended to use the protection circuit shown in the "Electrical Specifications" chapter in the Datasheet.

## 19 Digital-to-Analog Converter (DAC)

### 19.1 Introduction

This MCU is equipped with 2 12-bit digital-to-analog converter (DAC) unit, DAC1 and DAC2. Each DAC unit includes two DAC conversion channels that can operate independently or synchronously. The analog voltage output range has two selectable settings. Each conversion channel has an output amplifier to drive external loads directly without an external operational amplifier. Independent pin inputs for reference voltages VREFH and VREFL can improve conversion accuracy.

### 19.2 Features

- 2 DAC units, each with 2 DAC conversion channels.
- 12-bit conversion data can be configured as left- or right-aligned.
- Both conversion channels in the same DAC module can perform synchronous conversion.
- The data computing unit (DCU) can output triangular and sawtooth waves.
- The output can be used as the negative-end voltage for the voltage comparator (CMP).
- The output has amplification function and can drive external loads directly.
- The ADC conversion priority mode reduces interference during ADC conversion.
- Independent pin inputs for reference voltages VREFH/VREFL

### 19.3 Functional Description

#### 19.3.1 Function Block Diagram

Figure 19-1 DAC Conversion Channel Block Diagram

Table 19-1 DAC pin

| Pin Name | Input/Output | Function            |
|----------|--------------|---------------------|
| AVCC     | Input        | Analog Power Supply |
| AVSS     | Input        | Analog Ground       |
| VREFH    | Input        | Reference Voltage   |
| VREFL    | Input        | Reference Ground    |

| Pin Name  | Input/Output | Function                                  |
|-----------|--------------|-------------------------------------------|
| DACx_OUTy | Output       | DAC Converts Analog Output (x=1-2, y=1-2) |

**Note**

In subsequent sections of this chapter, x refers to the unit number, and y refers to the channel number.

### 19.3.2 DAC Conversion

Each conversion channel can perform DAC conversion independently. When DAC\_DACR.DAyE is set to 1, DAC conversion starts for the corresponding channel and the conversion result is output from DACx\_OUTy. If only the conversion result is used as the negative input voltage of the voltage comparator CMP, the DACx\_OUTy output can be turned off through the DAC\_DAOCR register. The DAC conversion action timing is as follows:

Figure 19-2 DAC Conversion Diagram

Using DAC1 Channel 1 for single-channel conversion as an example:

1. Set DAC conversion data (DAC\_DADR1) and data format (DAC\_DACR.DPSEL).
2. Set DAC\_DACR.DA1E to 1 to start DAC conversion. After the conversion time  $T_{st}$ , the conversion result is output from port DAC1\_OUT1 and is held until the value of DAC\_DADR1 is rewritten or DAC\_DACR.DA1E is set to 0. The output analog voltage can be calculated using the following formula:

$$DAC_{output} = \frac{\text{Conversion}}{4096} \times VREFH$$

When DAC\_DACR.DA1E is 1, rewriting DAC\_DADR1 triggers a new DAC conversion. In the same way, after conversion time  $T_{st}$ , the new conversion results are output from DAC1\_OUT1.

3. Setting DAC\_DACR.DA1E to 0 disables DAC1 Channel 1, and DAC1\_OUT1 outputs a high-impedance state.

### 19.3.3 Synchronization Conversion

Synchronized conversion of both channels in the same DAC unit can be achieved through synchronized updates of conversion data.

Taking the two-channel synchronized conversion using DAC1 as an example, this section describes the synchronization conversion process.

1. Set DAC conversion data (DAC\_DADR1, DAC\_DADR2) and data format (DAC\_DACR.DPSEL).
2. Set DAC\_DACR.DAE to 1 to start synchronous DAC conversion for both channels. After conversion time  $T_{st}$ , the conversion results are output from DAC1\_OUT1 and DAC1\_OUT2 and remain until DADR is rewritten or DAC\_DACR.DAE is set to 0.

- When DAC\_DACR.DAE is 1, simultaneously rewriting DAC\_DADRx1 and DAC\_DADRx2 triggers a new DAC conversion for both channels. In the same way, after conversion time  $T_{st}$ , the new conversion results are output from DAC1\_OUT1 and DAC1\_OUT2.
- Setting DAC\_DACR.DAE to 0 disables both channels, and DAC1\_OUT1 and DAC1\_OUT2 output a high-impedance state.

### 19.3.4 External Data Conversion

In addition to converting data in DAC\_DADRx, the DAC can also convert data from the data computing unit (DCU). DAC1 Channel 1 and Channel 2 correspond to DCU units 1 and 2, respectively, and DAC2 Channel 1 and Channel 2 correspond to DCU units 3 and 4, respectively. Setting DAC\_DACR.EXTDSL to 1 selects the lower 12 bits of data register 0 in the corresponding DCU unit for conversion.

When converting external data, the output amplifier and ADC conversion priority mode are disabled.

### 19.3.5 ADC Conversion Priority Mode

When the DAC starts conversion, a transient inrush current may occur on the analog power supply, which can interfere with ongoing ADC conversions. The ADC conversion priority mode actively avoids this interference by changing the update timing of DAC conversion data.

Setting DAC\_DAADPCR.ADPEN to 1 enables ADC conversion priority mode:

- If DAC\_DADRx is rewritten during ADC conversion, DAC conversion does not start immediately but waits until ADC conversion is complete. The maximum delay from rewriting DAC\_DADRx to starting DAC conversion is one ADC conversion period, during which the DAC\_DADRx value and analog output do not match.
- If DAC\_DADRx is rewritten when ADC is stopped (ADC\_STR.STRT=0), DAC conversion starts after 2 ADCLK periods.

DAC\_DAADPCR.ADCSLn (n=1-3) is used to select the ADC channel with priority for ADC conversion. The ADC conversion priority mode action timing is as follows:

Figure 19-3 ADC Conversion Priority Mode Action Schematic Diagram

**Note**

When converting external data (DAC\_DACR.EXTDSLy=1), ADC conversion priority mode is disabled.

The following takes DAC1 channel 1 as an example to introduce the steps for setting the ADC conversion priority mode.

1. Confirm ADC is stopped and set DAC\_DAADPCR.ADCSL1.
2. Confirm ADC is stopped and set DAC\_DACR.DA1E to 1.
3. Write conversion data to DAC\_DADR1.
  - When conversion data A is written to DAC\_DADR1, ADC\_STR.STRT=0 (ADC is stopped), and DAC conversion starts after 2 ADCLK periods.
  - When conversion data B is written to DAC\_DADR1, ADC\_STR.STRT=1 (ADC is converting), and DAC conversion starts after ADC conversion is complete. Conversion data C is written to DAC\_DADR1 before DAC conversion starts, so the final converted data is C, not B.

To avoid data loss, check DAC\_DAADPCR.DAySF register to confirm the current data conversion is complete before rewriting DAC\_DADRx.

## 19.4 Register Description

### 19.4.1 Register List

- DAC1 base address: 0x40041000
- DAC2 base address: 0x40041400

Table 19-2 Digital-to-Analog Converter (DAC) Register Offset

| Offset | Register    | Description                              | Width |
|--------|-------------|------------------------------------------|-------|
| 0x00   | DAC_DADR1   | Data Register 1                          | 16    |
| 0x02   | DAC_DADR2   | Data Register 2                          | 16    |
| 0x04   | DAC_DACR    | Control Register                         | 16    |
| 0x06   | DAC_DAADPCR | ADC Conversion Priority Control Register | 16    |
| 0x1C   | DAC_DAOCR   | Analog Output Control Register           | 16    |

### 19.4.2 Data Register (DAC\_DADRx) (y=1-2)

This register stores the data for DAC conversion, with one register per channel. As long as DAC conversion is enabled, the value in DAC\_DADRx is converted to an analog voltage and output from the analog port. 32-bit operations on DAC\_DADR1 can set the conversion data for both channels in the unit simultaneously.

Offset: 0x00 (DAC\_DADR1), 0x02 (DAC\_DADR2)

#### Data Right-aligned (DACR.DPSEL=0)

| Offset | Bit Position |    |    |    |      |    |   |   |   |   |   |   |   |   |   |   |

| 2     | DA2E     | Channel 2 Enabled                  | Bit setting valid when DAE=0: <ul style="list-style-type: none"> <li>0b0: Channel 2 disabled</li> <li>0b1: Channel 2 enabled</li> </ul>                                                  | RW     |
| 1     | DA1E     | Channel 1 Enabled                  | Bit setting valid when DAE=0: <ul style="list-style-type: none"> <li>0b0: Channel 1 disabled</li> <li>0b1: Channel 1 enabled</li> </ul>                                                  | RW     |
| 0     | DAE      | Total Channel Enabled              | <ul style="list-style-type: none"> <li>0b0: Channels 1, 2 disabled</li> <li>0b1: Channels 1, 2 enabled</li> </ul>                                                                        | RW     |

**Note**

- This register controls DAC conversion and DAC output; see the "[Analog Output Control Register \(DAC\\_DAOCR\)](#)" description for details.
- When DA1E=0 and DAE=0, channel 1 stops DAC conversion, the analog output is disabled regardless of DAAMP1, and the port presents a high-impedance state. When DA2E=0 and DAE=0, channel 2 stops DAC conversion, the analog output is disabled regardless of DAAMP2, and the port presents a high-impedance state.
- When using ADC conversion priority mode, set DA2E, DA1E, and DAE when ADC is stopped (ADC\_STR.STRT=0). To avoid accidental ADC startup, set the ADC trigger selection to software trigger.

## 19.4.4 Analog Output Control Register (DAC\_DAOCR)

| Offset | Bit Position |         |          |    |    |    |   |   |   |   |   |   |   |   |   |   |

| 7:3   | <i>Reserved</i> | <i>Reserved</i>                        | -                                                                                                                                                                                                 | -      |
| 2     | ADCSL3          | ADC_3 Priority Selection               | <ul style="list-style-type: none"> <li>0b0: Does not select ADC_3 as the ADC conversion priority object</li> <li>0b1: Selects ADC_3 as the ADC conversion priority object</li> </ul>              | RW     |
| 1     | ADCSL2          | ADC_2 Priority Selection               | <ul style="list-style-type: none"> <li>0b0: Does not select ADC_2 as the ADC conversion priority object</li> <li>0b1: Select ADC_2 as the ADC conversion priority object</li> </ul>               | RW     |
| 0     | ADCSL1          | ADC_1 Priority Selection               | <ul style="list-style-type: none"> <li>0b0: Does not select ADC_1 as the ADC conversion priority object</li> <li>0b1: Select ADC_1 as the ADC conversion priority object</li> </ul>               | RW     |

**Note**

- This register controls ADC conversion priority mode.
- When ADPEN is set to 1, ADC conversion priority mode is enable; select the ADC unit for priority when setting ADPEN.
- DA1SF and DA2SF are DA conversion status flag bits, reflecting whether the data in the current channel data register has been converted.

## 19.5 Precautions

### 19.5.1 Module Stop Function Settings

The module stop control register can set the DAC to be active or stopped. After system reset, the DAC is stopped and must be released from the module stop state before accessing the register. For specific descriptions, please refer to the relevant sections of the "Action Mode and Low Power Mode" section in the "Power Supply Control (PWC) " chapter.

### 19.5.2 DAC Action in Module Stop State

If the DAC enters the module stop state during conversion, the analog output is maintained, and the current through the analog power supply remains the same as during conversion. To further reduce power consumption in the module stop state, set both DAYE and DAE bits in DAC\_DACR register to 0.

### 19.5.3 DAC Action in Stop Low Power Mode

If the system enters Stop mode during DAC conversion, the analog output is maintained, and the current through the analog power supply remains the same as during conversion. To further reduce power consumption in Stop mode, set both DAYE and DAE bits in DAC\_DACR register to 0.

### 19.5.4 DAC Action in Power-Down Low Power Mode

If the system enters Power-down mode during DAC conversion, the analog output is set to a high-impedance state.

### 19.5.5 Using the Output Amplifier

Use the following initialization procedure when using the output amplifier.

**Step1.** Write all 0s to DAC\_DADRY.

**Step2.** Set DAC\_DACR.DAAMPY to 1.

**Step3.** Set DAC\_DACR.DAE or DAYE to 1.

**Step4.** Wait 3 $\mu$ s before writing the conversion data to DAC\_DADRY.

Turning off the DAC stops the amplifier. To use the amplifier again, repeat steps 1-4.

## 20 On-chip Temperature Sensor (OTS)

### 20.1 Introduction

The On-chip Temperature Sensor (hereinafter referred to as OTS) can obtain the temperature inside the chip to support the reliable operation of the system. OTS provides a set of temperature-related digital quantities, and the temperature value can be obtained through calculation. When not in use, it can be turned off by the module stop function to reduce system power consumption.

### 20.2 Functional Description

#### 20.2.1 Function Block Diagram

Figure 20-1 OTS Function Block Diagram

#### 20.2.2 Usage Method

Before using OTS to obtain the internal temperature of the chip, it must be calibrated first, and the measurement accuracy is related to the calibration method. Please refer to the following calibration experiment instructions for calibration. When using, please turn off the module stop function and start the internal low-speed clock LRC. At the same time, please choose to start the internal high-speed clock HRC, external high-speed clock XTAL and external low-speed clock XTAL32 according to the usage. After setting the register OTS\_CTL.OTSST to "1", the temperature measurement starts, and the OTSST bit will be automatically cleared after the temperature measurement is completed. After confirming that OTSST is "0", read the temperature parameters in registers OTS\_DR1, OTS\_DR2, and OTS\_ECR, and use the following calculation formula to obtain the temperature value.

$$T = K \times (1.7/D1 - 1/D2) \times E_{hrc} + M$$

Parameter Description:

- T: Temperature (°C)
- K: Temperature slope (determined by calibration experiment)

- D1: Temperature data 1 (read from register OTS\_DR1)
- D2: Temperature data 2 (read from register OTS\_DR2)
- $E_{hrc}$ : HRC frequency error compensation data (read from register OTS\_ECR)
- M: Temperature offset (determined by calibration experiment)

The register OTS\_CTL.OTSCK is used to select the temperature measurement clock. When the HRC action is selected, its frequency error may affect the accuracy of the final calculated temperature. To eliminate this error, start XTAL32 before measuring the temperature and use  $E_{hrc}$  when calibrating and calculating the temperature. When selecting XTAL action, ignore  $E_{hrc}$  and show it as a constant 1.

**Calibration Experiment:** Perform a calibration experiment at two determined temperatures and calculate K and M.

$$K = (T_2 - T_1) / (A_2 - A_1)$$

$$M = T_1 - K \times A_1 = T_2 - K \times A_2$$

Parameter Description:

- T1: Experimental temperature 1
- T2: Experimental temperature 2
- A1:  $(1.7/D1_{T1} - 1/D2_{T1}) \times E_{hrcT1}$   
 $D1_{T1}$ ,  $D1_{T1}$ ,  $E_{hrcT1}$  are D1, D2,  $E_{hrc}$  measured at temperature T1 respectively.
- A2:  $(1.7/D1_{T2} - 1/D2_{T2}) \times E_{hrcT2}$   
 $D1_{T2}$ ,  $D1_{T2}$ ,  $E_{hrcT2}$  are D1, D2,  $E_{hrc}$  measured at temperature T2 respectively.

For reference, three sets of temperature data are preset inside the chip, and the data of two temperature points can be arbitrarily selected for calibration. Since the test environment temperature may vary, the preset data is for reference only.

Table 20-1 OTS Preset Temperature Data

| Testing Temperature       | Reading Method          |                         | Testing Conditions |
|---------------------------|-------------------------|-------------------------|--------------------|
|                           | Temperature Data 1 (D1) | Temperature Data 2 (D2) |                    |
| $T_A = -40^\circ\text{C}$ | OTS_PDR3[15:0]          | OTS_PDR3[31:16]         | XTAL=8MHz          |
| $T_A = 25^\circ\text{C}$  | OTS_PDR1[15:0]          | OTS_PDR1[31:16]         | XTAL=8MHz          |
| $T_A = 125^\circ\text{C}$ | OTS_PDR2[15:0]          | OTS_PDR2[31:16]         | XTAL=8MHz          |

$E_{hrc}$  is a calibration value to eliminate the influence of HRC error on the measured temperature. It can be read from register OTS\_ECR. The usage is as follows:

Table 20-2  $E_{hrc}$  Usage and Setting Method

| Action Clock | Calibration Experiment (Calculate K, M) |                                   | Temperature Measurement           |
|--------------|-----------------------------------------|-----------------------------------|-----------------------------------|
| (OTSCK)      | Use Preset Temperature Data             | Re-acquire Temperature Data       | (Calculate T)                     |
| XTAL         | $E_{hrc} = 1$                           | $E_{hrc} = 1$                     | $E_{hrc} = 1$                     |
| HRC          | $E_{hrc} = f_{hrc}(MHz) / 0.032768$     | $E_{hrc} = \text{OTS\_ECR}[15:0]$ | $E_{hrc} = \text{OTS\_ECR}[15:0]$ |

**Note**

$f_{\text{hrc}}$  is the standard frequency of HRC, that is, 16MHz or 20MHz.

The register OTS\_CTL.TSSTP is used to select whether to turn off the analog temperature sensor after the temperature measurement is completed. The initial value of TSSTP is "0", which means that the analog temperature sensor is turned on after a temperature measurement is completed, so that the stabilization time of the analog temperature sensor from off to on will be automatically skipped in the next temperature measurement. To turn off the analog temperature sensor after each temperature measurement, please set TSSTP to "1".

The temperature measurement can be triggered by other of peripheral events. When using it, please set the trigger target of the trigger source to OTS. When the temperature measurement is completed, an event that triggers the start of other of peripherals or generated. When using it, please set the register OTS\_TRG to select the trigger target. Please set the register OTS\_CTL.OTSIE to "1" when using the temperature measurement completion interrupt.

## 21 Advanced Control Timer (Timer6)

### 21.1 Introduction

Advanced Control Timer 6 (Timer6) is a high-performance timer with 32/16-bit counting width, offering a rich and flexible combination of configurations suitable for various complex application scenarios. It supports multiple interrupts, events, and PWM outputs. This timer supports both sawtooth and triangular waveform modes and can generate various types of PWM signals (edge-aligned independent PWM, center-aligned independent PWM, center-aligned complementary PWM, and center-aligned asymmetric PWM, etc.). It enables both software and hardware synchronization between units (synchronized start, stop, clear, refresh, etc.). All reference registers support buffering (single-level and double-level buffering). Timer6 also supports pulse width and period measurement, 2-phase and 3-phase quadrature encoding count, and EMB control, units 1 through 5 and unit 7 support PTO (Pulse Train Output). This series of products is equipped with 8 units of Timer6 (unit 1 to unit 4 are 32-bit timers; unit 5 to unit 8 are 16-bit timers).

### 21.2 Features

The following table outlines the basic functions and features of Timer6.

**Table 21-1 Basic Functions and Features of Timer6**

|                  |                                   |
|------------------|-----------------------------------|

## 21.3 Functional Description

### 21.3.1 Timer6 Block Diagram

The basic block diagram of Timer6 is shown below. In the diagram, the symbol "<t>" denotes the unit number, which ranges from 1 to 8. In the remainder of this section, "<t>" will consistently refer to the unit number and will not be further explained.

Figure 21-1 Timer6 Basic Block Diagram

Table 21-2 : Timer6 Port List shows the input and output port list of Timer6.

Table 21-2 Timer6 Port List

| Port Name     | Direction    | Function                                                                                                                                                                                                               |

| TMR6_<t>_PWMB |              |                                                                                                                                                                                                                        |
| TMR6_TRIGA    | Input/Output | <ul style="list-style-type: none"> <li>Hardware count clock input port or capture input port</li> <li>Hardware start, stop, clear, refresh condition input port</li> <li>PTO Z phase output port</li> </ul>            |
| TMR6_TRIGB    |              |                                                                                                                                                                                                                        |
| TMR6_TRIGC    |              |                                                                                                                                                                                                                        |
| TMR6_TRIGD    |              |                                                                                                                                                                                                                        |

## 21.3.2 Basic Actions

### 21.3.2.1 Waveform Mode

Timer6 has two basic counting wave modes: Sawtooth wave mode and Triangle wave mode. The basic waveforms of the two waveform modes are shown below.

Figure 21-2 Sawtooth Waveform (Counting Up)

Figure 21-3 Triangle Waveform

### 21.3.2.2 Compare Output

Each unit's Timer6 has two compare output ports (TMR6\_<t>PWMA and TMR6\_<t>PWMB), which can output specified levels when the counter value matches the compare reference. The GCMAR and GCMBR registers correspond to the compare references for TMR6\_<t>PWMA and TMR6\_<t>PWMB, respectively. When the timer counter value equals GCMAR, the TMR6\_<t>PWMA or TMR6\_<t>PWMB port outputs the specified level.

The levels of the TMR6\_<t>PWMA port at the start of counting, stop of counting, counter overflow, and compare match can be set via the PCNAR.STACA, PCNAR.STPCA, PCNAR.OVFCA, PCNAR.UDFCA, PCNAR.CMA<B>U<D>A, and PCNAR.FORCA bits of the port control register (PCNAR).

The levels of the TMR6\_<t>PWMB port at the start of counting, stop of counting, counter overflow, and compare match can be set via the PCNBR.STACB, PCNBR.STPCB, PCNBR.OVFCEB, PCNBR.UDFCB, PCNBR.CMA<B>U<D>B, and PCNBR.FORCB bits of the port control register (PCNBR). The figure below illustrates an example of the compare output behavior.

Figure 21-4 Compare Output Action

### 21.3.2.3 Capture Input

Each unit features a capture input function and includes two sets of capture registers (GCMAR, GCMBR) for storing the current counter value upon capture. By setting the PCNA<B>.CAPMDA<B> bit to 1, the capture input function is enabled. When the specified capture condition is met and becomes active, the current counter value is stored in the corresponding capture register (GCMAR, GCMBR).

The conditions for each set of capture inputs of each unit can be internal trigger event inputs 0-3, port inputs of TMR6\_TRIGA-D, port inputs of TMR6\_<t>\_PWMA or TMR6\_<t>\_PWMB, and TMR6\_<t>\_XOR (port input XOR of TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB), etc. The specific condition selection can be set through the hardware capture event selection registers (HCPAR, HCPBR). The following figure shows an example of the capture input action.

Figure 21-5 Capture Input Action

### 21.3.3 Clock Source Selection

The Timer6 count clock can be selected from the following sources:

1. Divided PCLK0 by 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, or 1024 (configured via GCONR.CKDIV)
2. Internal trigger event inputs 0-3 (configured via HCUPR.HCUPn or HCDOR.HCDOn) (n=8-11)
3. Port inputs of TMR6\_TRIGA-D (configured via HCUPR.HCUPn or HCDOR.HCDOn) (n=16-23)
4. Quadrature encoder input of TMR6\_<t>PWMA and TMR6<t>\_PWMB (configured via HCUPR.HCUPn or HCDOR.HCDOn) (n=0-7)

When the clock source selection is set to 1, the timer operates in software counting mode. When set to others, the timer operates in hardware counting mode. Each count clock source is independent and can be enabled or disabled individually. When the hardware clocks are selected, the software clock is automatically disabled.

#### Note

In hardware count mode, the GCONR.CKDIV must be set to 0.

### 21.3.4 Count Direction

The counting direction of Timer6 can be changed via software. The method for changing the count direction varies slightly depending on the waveform mode.

#### 21.3.4.1 Sawtooth Wave Count Direction

In sawtooth wave mode, the counting direction can be configured either during timer operation or while the timer is stopped.

While counting up, setting GCONR.DIR=0b0 (count down) causes the timer to switch to down-counting mode after reaching an overflow. While counting down, setting GCONR.DIR=0b1 (count up) causes the timer to switch to up-counting mode after reaching an underflow.

When the timer is stopped, the GCONR.DIR setting can be applied immediately by also setting GCONR.FODIR=0b1. The setting of GCONR.DIR can be reflected in the counting direction immediately. After starting the counting, count according to the set GCONR.DIR. If GCONR.FODIR=0b0 is set together with GCONR.DIR, the setting of GCONR.DIR is reflected in the count from the start of the count until it overflows or underflows.

#### 21.3.4.2 Triangular Wave Count Direction

In triangle wave mode, setting the counting direction during operation is disabled. The timer automatically reverses the counting direction upon reaching the peak or valley of the count.

When the timer is stopped, setting the GCONR.DIR bit along with GCONR.FODIR=0b1, the setting of GCONR.DIR can be reflected in the counting direction immediately. After starting the counting, count according to the set GCONR.DIR. If GCONR.DIR is set with GCONR.FODIR=0b0, after the counting starts until the overflow or underflow occurs, the counting direction is automatically changed, and setting the GCONR.DIR bit is invalid.

### 21.3.5 Counter Refresh

Timer6 includes a General Refresh Value Register (UPDAR), which allows real-time refreshing of the General Counter Value Register (COUNTER) value either while the timer is stopped or during counting.

The conditions for refreshing the counter value are configured through the Hardware Refresh Event Selection Register (HUPDR) or the Software Synchronous Refresh Control Register (SUPDR). When a con-

figured refresh event is triggered, the value in the General Counter Value Register (CNTER) is updated with the value specified in the General Refresh Value Register (UPDAR). The figure below illustrates an example of hardware refresh action during counting in sawtooth wave mode.

Figure 21-6 Hardware Refresh Action

### 21.3.6 Digital Filtering

The TMR6\_<t>PWMA, TMR6\_<t>PWMB, and TMR6\_TRIGA-D port inputs are equipped with digital filtering functionality. The filter for the TMR6\_<t>PWMA and TMR6\_<t>PWMB ports can be enabled by setting the corresponding enable bits in the Filter Control Register (FCNCR). The filter reference clock used when the filter is active can also be configured via FCNCR. The TMR6\_TRIGA-D ports are shared among multiple units and their filter functionality can be enabled by setting the appropriate enable bits in the Common Filter Control Register (FCNTR). The filter reference clock used when the filter is active can also be configured via FCNTR.

When three consecutive identical levels are sampled on the port based on the filter sampling reference clock, the level is considered active and passed to the internal module. The fewer than three consecutive identical levels are treated as external noise and ignored and not be passed to the internal module. An example of this filtering behavior is shown in the figure below.

Figure 21-7 Digital Filtering Function of Capture Input Ports

## 21.3.7 Software Synchronization

### Software Synchronization Start

Each unit can achieve synchronous start of the target unit counter (COUNTER) by setting the relevant bits of the Software Synchronous Start Control Register (SSTAR).

In addition, the product is equipped with a count synchronization enable register TMR\_SYNENRx (x=1-2) to synchronously start all the timers (including Timer0, Timer2, Timer4, Timer6, TimerA) carried by the product. For usage details and register descriptions, refer to the General Timer (Timer0) chapter.

### Software Synchronization Stop

By setting the relevant bits in the Software Synchronization Stop Control Register (SSTPR), the target unit counter (COUNTER) can be synchronously stopped.

### Software Synchronization Clear

By setting the relevant bits in the Software Synchronization Clear Control Register (SCLRR), the target unit counter (COUNTER) can be synchronously cleared.

### Software Synchronization Refresh

By setting the relevant bits in the Software Synchronization Refresh Control Register (SUPDR), the target unit counter (COUNTER) can be synchronously refreshed.

As shown in the figure below, setting SSTAR.SSTA1=SSTAR.SSTA2=SSTAR.SSTA3=1 enables software-synchronized start for units 1-3. Similarly, setting SSTPR.SSTP1=SSTPR.SSTP2=SSTPR.SSTP3=1 enables software-synchronized stop for units 1-3.

The software synchronization action related registers (SSTAR, SSTPR, SCLRR and SUPDR) are a group of registers independent of the unit and shared among various units. Each bit of this group of registers is enable only when writing 1, and writing 0 has no effect. When the SSTAR register is read, the timer status of each unit (counting stopped or counting) is read. When the SSTPR, SCLRR, or SUPDR is read, zero is read.

Figure 21-8 Software Synchronization Action

### 21.3.8 Hardware Synchronization

Each unit is equipped with two special general input ports (TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB), and all units share 4 general external trigger input ports (TMR6\_TRIGA, TMR6\_TRIGB, TMR6\_TRIGC, and TMR6\_TRIGD), as well as 4 internal trigger event input conditions that enable hardware-synchronized operations across units.

Internal trigger event sources can be selected by configuring the corresponding bits in the Hardware Trigger Event Selection Registers, as described in the "Automatic Operation System (AOS)" chapter titled "Timer6 Hardware Trigger Event Selection Register (TMR6\_TRGSELx) (x=0-3)". For detailed event-to-source mapping, refer to the "Interrupt Controller (INTC)" chapter. When using internal trigger functions, the peripheral trigger function enable bit in PWC\_FCG0 Register must first be set to 1.

#### Hardware Synchronization Start

Each unit can choose to start the timer by hardware, and the unit with the same hardware starting condition can be started synchronously when the starting condition is valid. The hardware start condition is configured in the Hardware Start Event Selection Register (HSTAR).

#### Hardware Synchronization Stop

Each unit can choose to stop the timer by hardware, and the unit with the same hardware stop condition can be synchronized to stop when the stop condition is valid. The hardware stop condition is configured in the Hardware Stop Event Selection Register (HSTOPR).

### Hardware Synchronization Clear

Each unit can choose to clear the timer by hardware, and select the unit with the same hardware clear condition to achieve synchronous clear when the clear condition is valid. The hardware clear condition is configured in the Hardware Clear Event Selection Register (HCLRR).

### Hardware Synchronization Refresh

Each unit can choose to refresh the timer by hardware, and select the unit with the same hardware refresh conditions, synchronous refreshing can be achieved when the refresh conditions are valid. The hardware refresh condition is set in the Hardware Refresh Event Selection Register (HUPDR).

### Hardware Synchronization Capture Input

Each unit can choose to implement the capture input function by hardware, and the units with the same capture input function condition can synchronize the capture input when the capture input function condition is valid. The hardware capture input conditions are set using the Hardware Capture Event Selection Registers (HCPAR, HCPBR).

### Hardware Synchronization Count

Each unit can choose to use the hardware input as the CLOCK for counting. By selecting units with the same hardware counting conditions, synchronous counting can be achieved when the hardware counting clock is valid. The count conditions are configured via the Hardware Count Up Event Selection Register (HCUPR) and Hardware Count Down Event Selection Register (HCDOR).

Selecting a hardware synchronous count function only designates the external clock source. It does not affect the start, stop, or clear operations of the timer. These actions must be configured separately.

The diagram below illustrates a hardware synchronization example across Units 1-3.

Figure 21-9 Hardware Synchronization Action

### 21.3.9 Pulse Width Measurement

When using the hardware trigger related functions (refer to "[Hardware Synchronization](#)") of the TMR6\_TRIGA-D port and the TMR6\_<t>\_PWMA-B port, each unit can realize independent pulse width measurement functions.

For example, by configuring the hardware start condition of the counter as the rising edge of TMR6\_TRIGA, and setting the hardware clear condition, stop condition, and the capture input condition for the GCMAR register to the falling edge of TMR6\_TRIGA, continuous pulse width measurement can be achieved. The corresponding operation is illustrated in the figure below.

Figure 21-10 Pulse Width Measurement

### 21.3.10 Period Measurement

When using the hardware trigger related functions (refer to "[Hardware Synchronization](#)") of the TMR6\_TRIGA-Dport and the TMR6\_<t>\_PWMA-B port, each unit can realize independent period measurement functions.

For example, by configuring the hardware start condition, hardware clear condition, and the capture input condition for the GCMBR register all to the rising edge of TMR6\_TRIGB, continuous period measurement can be achieved. The corresponding operation is illustrated in the figure below.

Figure 21-11 Period Measurement

### 21.3.11 Buffer Function

Timer6 supports buffer function for general period reference value, general compare reference value, special compare reference value, dead-time reference value, and more. This allows for hardware-based updates to the period, duty period, and dead time during counting. The period reference value, general compare reference value, and special compare reference value support single or double buffer function, while the dead-time reference value supports single buffer function.

### 21.3.11.1 Single Buffer Action

Single buffer action refers to configuring the buffer control register (BCONR.BE-NA<B><P><SPA><SPB>=1, BCONR.BSEA<B><P><SPA><SPB>=0) and the dead-time control register (DCONR.DTBENU<D>=1), at the buffer transfer time point, select the following events to occur:

1. The value in the General Period Reference Value Buffer Register (PERBR) is automatically transferred to the General Period Reference Value Register (PERAR).
2. The values in the General Compare Reference Value Buffer Registers (GCMCR, GCMDR) are automatically transferred to the General Compare Reference Value Registers (GCMAR, GCMBR) during compare output operations.
3. The values in the General Compare Reference Value Registers (GCMAR, GCMBR) are automatically transferred to the General Compare Reference Value Buffer Registers (GCMCR, GCMDR) during capture input operations.
4. The values in the Special Compare Reference Value Buffer Registers (SCMCR, SCMDR) are automatically transferred to the Special Compare Reference Value Registers (SCMAR, SCMBR).
5. The values in the Dead-Time Reference Value Buffer Registers (DTUBR, DTDBR) are automatically transferred to the Dead-Time Reference Value Registers (DTUAR, DTDAR).

The figure below shows the timing diagram of single buffer operation for general compare reference value registers during a compare output operation in Unit 1 (PCNAR.CAPMDA=0). From the diagram, it can be seen that changing the General Compare Reference Value Register (GCMAR) value during counting allows adjustment of the output duty period, while changing the General Period Reference Value Register (PERAR) value adjusts the output period.

Figure 21-12 Timing Diagram of Compare Output in Single Buffer Mode

### 21.3.11.2 Double Buffer Action

Double buffer operation refers to the configuration where both BCONR.BENA<B><P><SPA><SPB>=1 and BCONR.BSEA<B><P><SPA><SPB>=1 are set. At the buffer transfer timing point, the following events occur:

1. The value in the General Period Reference Value Buffer Register (PERBR) is automatically transferred to the General Period Reference Value Register (PERAR), and the value in the General Period Reference Value Double Buffer Register (PERCR) is automatically transferred to General Period Reference Value Buffer Register (PERBR).
2. The values in the General Compare Reference Value Buffer Registers (GCMCR, GCMDR) are automatically transferred to the General Compare Reference Value Registers (GCMAR, GCMBR), and the values in the General Compare Reference Value Double Buffer Registers (GCMER, GCMFR) are automatically transferred to General Compare Reference Value Buffer Registers (GCMCR, GCMDR) during compare output operations.
3. The values in the General Compare Reference Value Buffer Registers (GCMCR, GCMDR) are automatically transferred to General Compare Reference Value Double Buffer Registers (GCMER, GCMFR), and the values in General Compare Reference Value Registers (GCMAR, GCMBR) are automatically transferred to General Compare Reference Value Buffer Registers (GCMCR, GCMDR) during capture input operations.
4. The values in the Special Compare Reference Value Buffer Registers (SCMCR, SCMDR) are automatically transferred to the Special Compare Reference Value Registers (SCMAR, SCMBR), and the values

in the Special Compare Reference Value Double Buffer Registers (SCMER, SCMFR) are automatically transferred to Special Compare Reference Value Buffer Registers (SCMCR, SCMDR).

The diagram below illustrates the timing of capture input in double buffer mode, triggered by Internal Trigger Event 0.

Figure 21-13 Capture Input Timing in Double Buffer Mode

### 21.3.11.3 Buffer Transfer Node

#### Compare Output (Sawtooth Wave) Buffer Transfer

When the buffer function is enabled (BCONR.BENA<B><P><SPA><SPB>=1, DCONR.DTBENU<D>=1) and compare output counting (PCNA<B>R.CAPMDA<B>=0) and the sawtooth wave count mode (GCONR.MODE=0), buffer transfers for the general period reference value, general compare reference value, special compare reference value, and dead-time reference value occur at either the counter overflow in up-counting mode or the counter underflow in down-counting mode.

The diagram below illustrates the buffer operation during up-counting in sawtooth mode:

Figure 21-14 Count Buffer Operation in Sawtooth Mode

**Note**

- If a clear operation occurs in sawtooth mode, it is treated as a counter overflow. At this moment, each reference will be transferred based on the corresponding buffer configuration (single buffer, double buffer, etc.).
- In hardware count mode, a clear operation is also treated as a counter overflow. In such cases, only the general period and general compare reference value are transferred based on the corresponding buffer configuration (single buffer, double buffer, overflow transfer, underflow transfer, etc.); other references are not transferred.

**Compare Output (Triangle Wave) Buffer Transfer**

When the buffer function is enabled (BCONR.BENA<B><P><SPA><SPB>=1, DCONR.DTBENU<D>=1) and compare output count (PCNA<B>R.CAPMDA<B>=0) and triangle wave count mode (GCONR.MODE=1), the buffer transfer timing for general period reference value, general compare reference value, special compare reference value, and dead-time reference value is controlled by corresponding control bits in the registers. When BCONR.BTRUA<B><P><SPA><SPB>=1 or DCONR.DTBTRU=1, buffer transfer occurs at the peak point of the triangle wave. When BCONR.BTRDA<B><P><SPA><SPB>=1 or DCONR.DTBTRD=1, buffer transfer occurs at the valley point of the triangle wave.

Figure 21-15 : Count Buffer Operation 1 in Triangle Mode shows the buffer action when the triangular wave count reaches the valley point. Figure 21-16 : Count Buffer Operation 2 in Triangle Mode is a diagram shows the buffer action when the triangular wave count reaches the peak point and valley point.

Figure 21-15 Count Buffer Operation 1 in Triangle Mode

Figure 21-16 Count Buffer Operation 2 in Triangle Mode

## Capture Input Buffer Transfer

When capture input action ( $PCNA\langle B\rangle.R.CAPMDA\langle B\rangle=1$ ) is valid, the general compare reference value support buffer transfer. If buffer configuration is enable ( $BCONR.BENA\langle B\rangle=1$ ), a buffer transfer occurs at each capture input action. Capture input action supports both single buffer and double buffer modes (which are controlled by the  $BCONR.BSEA\langle B\rangle$  setting).

## 21.3.12 General PWM Output

### 21.3.12.1 Single-Edge Aligned Independent PWM Output

In sawtooth wave count mode ( $GCONR.MODE=0$ ), each unit's two ports  $TMR6\_<t>\_PWMA$  and  $TMR6\_<t>\_PWMB$  can independently output PWM signals. When the same output level transition is configured at the counter overflow point, single-edge aligned independent PWM output can be achieved.

Figure 21-17 Single-Edge Aligned Independent PWM

### 21.3.12.2 Double-Edge Symmetrical Independent PWM Output

In triangle wave count mode ( $GCONR.MODE=1$ ), each unit's two ports  $TMR6\_<t>\_PWMA$  and  $TMR6\_<t>\_PWMB$  can independently output PWM signals. When level changes are configured at the count comparison match points, and the levels remain unchanged at the count peak and valley points, double-edge symmetrical independent PWM output can be achieved. The following figure shows that the  $TMR6\_<t>\_PWMA$  port and  $TMR6\_<t>\_PWMB$  port implement double-edge symmetrical independent output PWM.

Figure 21-18 Double-Edge Symmetrical independent PWM

### 21.3.12.3 Double-Edge Symmetrical Complementary PWM Output

In triangle wave count mode (GCONR.MODE=1), by configuring the level states for the ports during count start, comparison match, and count overflow, a pair of complementary PWM waveforms can be output on the TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB ports.

According to the different ways of assigning the GCMBR reference value, the output of double-edge symmetrical complementary PWM can be divided into "software-set GCMBR complementary PWM output" and "hardware-set GCMBR complementary PWM output".

#### Software-Set GCMBR Complementary PWM Output

Software setting means that in triangle wave mode, the general compare reference value register (GCMBR) used for the waveform output of the TMR6\_<t>\_PWMB port is directly written by the CPU, etc., and has no direct relationship with the value of GCMAR.

**Figure 21-19 Software-Set GCMBR Complementary PWM Output**

## Hardware-Set GCMBR Complementary PWM Output

The hardware setting means that in the triangle wave mode, the value of the general compare reference value register (GCMBR) used for the waveform output of the TMR6\_<t>\_PWMB port is determined by the value operation of the general compare reference value register (GCMAR) and the dead-time reference value register (DTU<D>AR) .

**Figure 21-20 Hardware-Set GCMBR Complementary PWM Output**

### 21.3.12.4 Double-Edge Asymmetrical PWM Output

In triangle wave count mode (GCONR.MODE=1), each unit's two ports, TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB, are capable of independently outputting PWM waveforms. Each port can change its output levels according to the corresponding comparison results based on the General Compare Reference Value Registers (GCMAR, GCMBR). If during the up-counting and down-counting phases of the counter, the level transitions on the TMR6\_<t>\_PWMA port are controlled by the comparison results of the GCMAR and GCMBR registers, a double-edge asymmetrical PWM output can be achieved on the TMR6\_<t>\_PWMA port. Below is the diagram for the double-edge asymmetrical PWM output on the TMR6\_<t>\_PWMA port:

Figure 21-21 Double-Edge Asymmetrical PWM Output

### 21.3.12.5 Multi-Phase PWM Output between Units

The TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB ports of each unit can output 2-phase PWM waves. By combining multiple units and combining software and hardware synchronization actions, multi-phase PWM wave output can be achieved. [Figure 21-22 : Single-Edge Aligned Independent PWM](#) shows the single-edge aligned independent PWM output by the combination of Unit 1 and Unit 2. [Figure 21-23 : Double-Edge Symmetrical Complementary PWM with Dead Time](#) shows the double-edge symmetrical complementary PWM output by the combination of Unit 1 and Unit 2.

Figure 21-22 Single-Edge Aligned Independent PWM

Figure 21-23 Double-Edge Symmetrical Complementary PWM with Dead Time

### 21.3.13 Quadrature Encoding Count

The TMR6\_<t>\_PWMA input is treated as the AIN input, the TMR6\_<t>\_PWMB input as the BIN input, and any input in TMR6\_TRIGA-D is treated as the ZIN input. With this configuration, Timer6 can implement quadrature encoding counting with three inputs.

For a single unit, the AIN and BIN inputs can independently perform position counting mode. For two units, the combination of AIN, BIN, and ZIN enables revolution counting mode, with one unit used for position counting and the other for revolution counting.

In revolution counting mode, the 8 units of Timer6 can be freely combined to act as either position counting or revolution counting units. However, when the Z phase masking function is enabled, the combinations are fixed as follows: Units 1 and 2 are combined, with Unit 1 as the position counting unit and Unit 2 as the revolution counting unit, each performing position and revolution counting respectively. Units 3 and 4 are combined, with Unit 3 as the position counting unit and Unit 4 as the revolution counting unit, each performing position and revolution counting respectively. Units 5 and

6 are combined, with Unit 5 as the position counting unit and Unit 6 as the revolution counting unit, each performing position and revolution counting respectively. Units 7 and 8 are combined, with Unit 7 as the position counting unit and Unit 8 as the revolution counting unit, each performing position and revolution counting respectively.

The counting conditions for AIN and BIN are determined by setting the quadrature relationship of TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB in the Hardware Count Up Event Selection Register (HCUPR) and Hardware Count Down Event Selection Register (HCDOR). The input action for ZIN is controlled by setting the Hardware Clear Event Selection Register (HCLRR) of the position unit to clear the position timer of the position counting unit, and the Hardware Count Up Event Selection Register (HCUPR) of the revolution unit to count the revolution timer of the revolution counting unit.

### 21.3.13.1 Position Counting Mode

The quadrature encoder position counting mode enables the implementation of basic counting, phase difference counting, and direction counting based on the input signals from AIN and BIN.

#### Basic Counting

Basic counting uses the input clock from either the AIN or BIN port to count.

Figure 21-24 Position Mode-Basic Counting

#### Phase Difference Counting

Phase difference counting operates based on the phase relationship between AIN and BIN. Depending on the configuration, the system can perform 1x counting, 2x counting, or 4x counting.

HCUPR.HCUP6=0b1 && HCDOR.HCDO4=0b1

Figure 21-25 Position Counting Mode-Phase Difference Counting (1x Counting)

HCUPR.HCUP6=HCUPR.HCUP5=0b1 && HCDOR.HCDO2=HCDOR.HCDO1=0b1

Figure 21-26 Position Counting Mode-Phase Difference Counting (2x Counting)

HCUPR.HCUP6=HCUPR.HCUP5=HCUPR.HCUP3=HCUPR.HCUP0=0b1  
HCDOR.HCDO7=HCDOR.HCDO4=HCDOR.HCDO2=HCDOR.HCDO1=0b1

Figure 21-27 Position Counting Mode-Phase Difference Counting (4x Counting)

### Direction Counting

Direction counting sets the AIN input as the direction control, and uses the BIN input as the counting clock.

HCUPR.HCUP2=0b1 && HCDOR.HCDO0=0b1

Figure 21-28 Position Counting Mode-Direction Counting

### 21.3.13.2 Revolution Counting Mode

The quadrature encoder revolution counting mode adds ZIN input events to the basic AIN/BIN counting mechanism to support features such as revolution count tracking. In this mode, depending on the revolution timer's counting method, the following functionalities can be realized: Z-phase counting, position overflow counting, and mixed counting.

#### Z-phase Counting

Z-phase counting refers to a counting operation in which the revolution counting unit counting based on the ZIN input signal, while the position counting unit is reset to zero.

Figure 21-29 Revolution Counting Mode-Z-phase Counting

### Position Overflow Counting

Position overflow counting refers to the condition where the position counting unit generates an overflow or underflow event, which then triggers the revolution counting unit to count once (In this counting mode, the ZIN input does not trigger counting in the revolution counting unit or clear in the position counting unit).

The overflow event from the position counting unit is routed via the internal trigger event interface to the revolution counting unit. This enables position overflow counting. Select a bit from Bit8-Bit11 in the Hardware Count Up Event Selection Register (HCUPR) or Hardware Count Down Event Selection Register (HCDOR) of the revolution counting unit. Set the event number in the Hardware Trigger Event Selection Register (TMR6\_TRGSELx, x=0-3) to the overflow or underflow event of the position counting unit. For details on the register settings, refer to the chapter "Automatic Operation System (AOS) : Timer6 Hardware Trigger Event Selection Register (TMR6\_TRGSELx) (x=0-3)". For event-to-interrupt mapping, refer to the "Interrupt Controller (INTC)" chapter.

Figure 21-30 Revolution Counting Mode-Position Overflow Counting

### Mixed Counting

Mixed counting refers to a combined counting method that integrates both Z-phase counting and position overflow counting. Its implementation method is also a combination of the above two counting methods.

Figure 21-31 Revolution Counting Mode-Mixed Counting

### 21.3.13.3 Z-Phase Action Mask

In the Z-phase counting function or mixed counting function of the revolution counting mode, you can set a few periods after the overflow point or underflow point of the position timer (GCONR.ZMSKVA setting) to mask the active input of ZIN and not count the revolution counting unit and clear the position counting unit.

When GCONR.ZMSKPOS bit of the position counting unit is 1, the Z-phase mask function of the position counting unit is enabled, and the number of periods of Z-phase mask is set by GCONR.ZMSKVAL; when GCONR.ZMSKREV bit of the revolution counting unit is 1, the Z-phase mask function of the revolution counting unit is enabled.

Figure below shows the mixed counting in the revolution counting mode. When there is a ZIN phase input within 4 counting periods after the position counting unit overflows, the action of the ZIN phase input is invalid, that is, the revolution counting unit does not count and the position counting unit is not cleared; the subsequent ZIN phase input acts normally.

Figure 21-32 Revolution Counting Mode-Mixed Count Z-Phase Masking Action Instances 1

The figure below illustrates an example of mixed counting in revolution counting mode, where a change in counting direction occurs in the third period after the position counting unit overflows. As a result, the configured masking period of four periods becomes inactive (the Z-phase masking is actively applied for only three periods) before the counter begins down-counting. After a count underflow occurs in the position counting unit, the Z-phase masking function is re-enabled, lasting for four periods before becoming inactive. During the Z-phase masking period, ZIN input is ignored, that is, the revolution counting unit does not count, and the position counting unit is not cleared. Any subsequent ZIN input will be processed normally.

Figure 21-33 Revolution Counting Mode-Mixed Count Z-Phase Masking Action Instances 2

### 21.3.14 Periodic Interval Response

Timer6 features two Special Compare Reference Value Registers (SCMAR and SCMBR), which, upon compare match, can respectively generate Special Compare Match Interrupt A and Special Compare Match Interrupt B signals to the INTTC, thereby triggering corresponding interrupts. Simultaneously, Special Compare Match Event A and Event B signals can be output to coordinate with other modules—commonly used for triggering operations such as ADC conversions.

These interrupts and event request signals can be configured to become active only once every few periods, thus realizing periodic interval response. This functionality is enabled by setting the VPERR.PCNTE and VPERR.SPPERIA/B bits. Set the VPERR.PCNTS bit to specify how many period the request signal is valid. In other period, even if the count value is equal to the value of the special comparison reference value register SCMAR or SCMBR, no valid request signal will be output.

When this feature is enabled, period match interrupts and events in all waveform modes will only be triggered during active periods of special comparison match interrupts and events output (i.e., when STFLR.VPERNUM=0 in the diagram below). The diagram below illustrates the operation of active request signals at periodic intervals.

Figure 21-34 Periodic Interval Active Request Signal Behavior

### 21.3.15 EMB Control

Timer6 provides protection control for port output states, allowing the port states to be forced into a predefined safe state when an abnormal condition occurs. All units share 4 common port output control interfaces. Each unit can select the EMB event connection interfaces via the Port Control Register (PCNA<B>.EMBSA<B>), which connects to a group of EMB events from the EMB module. The abnormal conditions enabled on the interface can be configured from the EMB side (refer to the EMB chapter). When an abnormal condition is detected on these interfaces, control of the general-purpose PWM output can be performed accordingly.

During normal operation, if an EMB event is detected from the EMB module, the port output state can be switched to a predefined state. When an EMB abnormal event occurs, the PWM output port can be forced into one of the following output states: high-impedance, output low-level, or output high-level, depending on the configuration of PCNA<B>.EMBCA<B>. For example, if PCNAR.EMBCA=0b01, and an

EMB event occurs during normal output on the TMR6\_<t>\_PWMA port, the output on this port will switch to a high-impedance state.

After the EMB event is invalid (i.e., the abnormal event connected from the EMB module to Timer6 disappears and the signal returns to a normal level), the PWM port output can automatically resume normal operation. At this point, the normal output of PWM can be selected through the Port Control Register (PCNA<B>R.EMBRA<B>=0b00; this is referred to as One Shot release) or restore the normal output of the PWM after counting to the next overflow point (PCNA<B>R.EMBRA<B>=0b01, 0b10, or 0b11, this is referred to as Cycle By Cycle release).

### 21.3.16 PTO Function

By setting TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB as AB-phase outputs and using any of the TMR6\_TRI-GA-D as the Z-phase output, Timer6 can implement the PTO ABZ three-phase output.

The PTO algorithm period is set via TMR6\_PERAR. The next period's TMR6\_PTNUMR and TMR6\_PTPERR write-in time points are configured by setting GCMAR/GCMBR. With ICONR.INTENA/INTENB set to 1, the counting mode is set to sawtooth wave mode (GCONR.MODE=0), and the counting direction is set to up (GCMONR.DIR=1). TMR6\_PTCTLR.PTOENA controls the entry of Timer6 into the PTO mode. The three enable switches, TMR6\_PTCTLR.AOUTENA, TMR6\_PTCTLR.BOUTENA, and TMR6\_PTCTLR.ZOUTENA, control the output of the ABZ phases.

#### 21.3.16.1 AB-phase Output

The output phase difference of the AB phase is related to the number of pulses in the algorithm period TMR6\_PTNUMR.Bit31.

#### Forward Rotation

When TMR6\_PTNUMR[31] is 0, it indicates forward rotation. The AB-phase outputs follow the period of PTAOPR[3:0] and PTBOPR[3:0], in the sequence of Bit0 -> Bit1 -> Bit2 -> Bit3 -> Bit0 -> Bit1...

Figure 21-35 Forward Rotation AB Output Timing

### Reversal Rotation

When TMR6\_PTNUMR[31] is 1, it indicates reverse rotation. The AB-phase outputs follow the period of PTAOPR[3:0] and PTBOPR[3:0], in the sequence of Bit3 -> Bit2 -> Bit1 -> Bit0 -> Bit3 -> Bit2...

Figure 21-36 Reverse Rotation AB Output Timing

## Forward to Reverse Rotation

At the end of the current algorithm period, if the rotation direction reverses in the next period, when switching from forward to a reverse rotation, the AB-phase outputs follow the period of PTAOPR[3:0] and PTBOPR[3:0] in the sequence of Bit0 -> Bit1 -> Bit2 -> Bit3 -> Bit3 -> Bit2 -> Bit1 -> Bit0... Similarly, when transitioning from reverse to forward rotation, the AB-phase outputs follow the sequence of PTAOPR[3:0] and PTBOPR[3:0] in Bit3 -> Bit2 -> Bit1 -> Bit0 -> Bit0 -> Bit1 -> Bit2 -> Bit3...

Figure 21-37 Forward to Reverse Rotation

### 21.3.16.2 Z-Phase Output

#### Z-Phase Output (Non-Compressed)

The TMR6\_PTZPER register sets the number of pulses per full rotation. When the position counter reaches TMR6\_PTZPER-1, it automatically resets to zero on the next clock period. The Z-phase output is position-dependent. During forward rotation, when the position counter reaches TMR6\_PTZOSPR, the Z output goes high; when it reaches TMR6\_PTZOEPR, the Z output goes low, as shown in the figure below. In theory, TMR6\_PTZOSPR and TMR6\_PTZOEPR must be less than TMR6\_PTZPERR; otherwise, the Z-phase output will be disabled.

Figure 21-38 Forward Rotation Z Output ( $PTZOSPR < PTZOEPR$ )

During reverse rotation, when the position counter reaches TMR6\_PTZOEPR, the Z output goes high; when it reaches TMR6\_PTZOSPR, the Z output goes low, as illustrated below.

Figure 21-39 Reverse Rotation Z Output ( $PTZOSPR > PTZOEPR$ )

If the current algorithm period is forward rotation, and the next period is reverse rotation, and the last pulse position of the current algorithm period equals PTZOSPR, the Z-phase output behaves as shown below.

Figure 21-40 Forward-to-Reverse Rotation Z Output (PTZOSPR=PTZOEPR)

### Z-Phase Output (Compressed)

Z-phase output supports CLK-level compression. Once the Z output position is specified, the TMR6\_PTZCMPBR.ZCMPB register can be configured to define the compression range. Enable CLK compression via the TMR6\_PTZCMPBR.ZCMPBENA register.

Since the TMR6\_PTPER value is dynamic, the configuration of TMR6\_PTZCMPBR.ZCMPB must satisfy the following condition:

When PTZOSPR equals PTZOEPR, the following constraint must be met:  $\text{TMR6\_PTZCMPBR.ZCMPB} < (\text{TMR6\_PTPER}_{\min}/2)$ , otherwise the compression function will not take effect. When  $\text{PTZOSPR} \neq \text{PTZOEPR}$ , this constraint does not apply.

The compression function is illustrated as follows:

Figure 21-41 Forward Rotation Z Output Compressed

Figure 21-42 Reverse Z-phase Output Compressed

Figure 21-43 Forward and Reverse Z-phase Output Compressed

### 21.3.16.3 Remainder Processing

Since pulse period=algorithm period/number of pulses, the calculation of the pulse period in software may produce a remainder. If this remainder is discarded, the AB-phase signals will maintain their last output state until the end of the algorithm period. As illustrated below, for example: Algorithm period (0x 41EF) /Number of pulses (0x 12C) =Pulse period (0x 42), with a remainder of 0x C8. If the remainder is not compensated, the AB-phase signals will remain unchanged during the last 200 clock periods of the algorithm period.

Figure 21-44 AB Output (Without Remainder Compensation)

To address this, the TMR6\_PTRMDR register can be used to pass the remainder to hardware. In this case, the first 200 pulse periods are set to 0x 42, and the last 100 pulse periods are set to 0x 41. This actively distributes the remainder across the first 200 pulses, each pulse compensates for one clock cycle, and there will be no 200 clock cycle gap period after the AB output stops at the end of the algorithm cycle as shown in the above figure.

Figure 21-45 AB Output (With Remainder Compensation)

21.3.16.4 Position Memory

PTPCPR and PTPCTR are read-only registers that store position information, ABZ port levels, and rotation direction. Before performing a reset or any operation that may result in the loss of PTO information, the contents of PTPCPR and PTPCTR should be read and saved. After the operation is completed, the saved data can be written back to the corresponding PTPSPR and PTPSTR registers to restore the position and ABZ port level information to their pre-reset state. Once this restoration is complete, the PTO function can be re-enabled using the previous configuration. By setting TMR6\_GCONR.START to 1, the ABZ output and position tracking will resume based on the restored data.

### 21.3.17 Function Summary Table

The following table summarizes the main features of Timer6 in Sawtooth and Triangle A/B wave modes.

**Table 21-3 Function Compare Table in Different Modes**

| PWM Output Function      |                      |                         |                          | Sawtooth Wave | Triangle Wave | Related Main Registers                                         |
|--------------------------|----------------------|-------------------------|--------------------------|---------------|---------------|----------------------------------------------------------------|
| Independent PWM Output   | Port State Control   | On Start                |                          | Support       | Support       | PCNA<B>R.STACA<B>                                              |

## 21.3.18 Interrupt and Events

### 21.3.18.1 Interrupt

Timer6 contains 6 general count compare match interrupts (including 2 capture input interrupts), 2 special count compare match interrupts, 2 count period match interrupts, and 1 dead time error interrupt.

#### Count Compare Match Interrupt

There are 6 general compare reference value registers (GCMAR-GCMFR), which can be compared with the count value to generate a comparison match. When the count compare matches, the STFLR.CMAF-STFLR.CMFF bits will be set to 1 respectively. At this time, if the corresponding bit in ICONR.INTENA-INTENF is set to 1 to enable interrupt, the corresponding interrupt request (TMR6\_<t>\_GCMA-F) will also be triggered.

When the capture input active condition selected by the hardware capture event selection register (HCPAR, HCPBR) occurs, the capture input action occurs. At this time, if the ICONR.INTENA or ICONR.INTENB bit is set to 1 to enable interrupt, the corresponding interrupt request (TMR6\_<t>\_GCMA-B) is triggered.

Two special compare reference value registers (SCMAR-SCMBR) can also be compared with the count value to generate a comparison match. When the count compare matches, the STFLR.CMSPAF-CMSPBF bits will be set to 1 respectively. At this time, if the corresponding bit in ICONR.INTENSAU<D> or ICONR.INTENSBUS<D> is set to 1 to enable interrupt, the corresponding interrupt request (TMR6\_<t>\_SCMA-B) will also be triggered.

#### Count Period Match Interrupt

When the sawtooth wave counts up to the overflow point, the sawtooth wave counts down to the underflow point, the triangle wave counts to the valley point, or the triangle wave counts to the peak point, the STFLR.OVFF or STFLR.UFFF bit will be set to 1. At this time, if the ICONR.INTENOVF or ICONR.INTENUDF bit is set to enable interrupt, the count period match interrupt (TMR6\_<t>\_GOVF and TMR6\_<t>\_GUDF) can be triggered at the corresponding time point.

#### Dead Time Error Interrupt

When the value of the dead time reference value register (DTU<D>AR) is loaded into the general compare reference value register (GCMBR), if it exceeds the period limit, a dead time error will occur, and the STFLR.DTEF bit will be set to 1. At this time, if the ICONR.INTENDTE bit is set to enable interrupts, the dead time error interrupt (TMR6\_<t>\_GDTE) will be triggered at this moment.

### 21.3.18.2 Events

During the clock counting process, if a period match event (overflow or underflow point of sawtooth wave, counting peak or valley point of triangle wave), general count comparison match event, or special count comparison match event occurs, a corresponding event output signal will be generated to select and trigger other modules, such as ADC, DMA, etc.

The following figure is an action example of general comparison match interrupt A-F&&event A-F (TMR6\_1\_GCMA-F), special comparison match interrupt A-B&&event A-B (TMR6\_1\_SCMA-B), and period match interrupt&&event (TMR6\_1\_GOVF) of unit 1.

Figure 21-46 Interrupt & Event Output Example in Sawtooth Wave Mode

## 21.4 Operation Example

The following describes the basic settings of Timer6 related registers in several typical application cases for user reference.

### 21.4.1 Basic Counting and Interrupt Action

- Step1.** Set the general period reference value (PERAR);
- Step2.** Set the required compare reference value, including the general compare reference value (GCMAR-GCMFR), the special compare reference value (SCMAR-SCMBR), etc.;
- Step3.** Set the required interrupt enable bit, including the count overflow interrupt (ICONR.INTENOVF), the count underflow interrupt (ICONR.INTENUDF), the count match interrupt (ICONR.INTENA-F, ICONR.INTENSAU, ICONR.INTENSAD, ICONR.INTENSBU, ICONR.INTENSBD), etc.;
- Step4.** Set the internal count clock division (GCONR.CKDIV);
- Step5.** Set the waveform mode (GCONR.MODE);
- Step6.** Set the counting direction (only required when the sawtooth wave mode GCONR.MODE=0);
- Step7.** Start the counter (GCONR.START=1).

### 21.4.2 Compare Output and Interrupt Action

- Step1.** Set the general period reference value (PERAR);
- Step2.** Set the compare reference of each channel, including the general compare reference value A (GCMAR) and the general compare reference value B (GCMBR);
- Step3.** Set the required interrupt enable bits, including count overflow interrupt (ICONR.INTENOVF), count underflow interrupt (ICONR.INTENUDF), count match interrupt (ICONR.INTENA-B), etc.;
- Step4.** Set the port output status for each channel in different counting states (refer to Bit17-Bit0 of PCNAR or PCNBR for related control);
- Step5.** Set internal count clock frequency division (GCONR.CKDIV);
- Step6.** Set the waveform mode (GCONR.MODE);
- Step7.** Set the counting direction (only required in sawtooth wave mode when GCONR.MODE=0);
- Step8.** Set the comparison output mode of each channel (PCNAR.CAPMDA=0, PCNBR.CAPMDB=0);
- Step9.** Set each channel output enable (PCNAR.OUTENA=1, PCNBR.OUTENB=1);
- Step10.** Start the counter (GCONR.START=1).

### 21.4.3 Capture Input and Interrupt Action

- Step1.** Set the general period reference value (PERAR);
- Step2.** Set the required interrupt enable bits, including the counter overflow interrupt (ICONR.INTENOVF), counter underflow interrupt (ICONR.INTENUDF), and capture input interrupts (ICONR.INTENA-B), etc.;
- Step3.** Set the capture input external conditions for each channel (refer to all active control bits in HCPAR or HCPBR. These active control bits are independent of each other, and multiple conditions can be selected simultaneously to serve as capture input conditions for a single channel);
- Step4.** Set the internal counter clock division (GCONR.CKDIV);
- Step5.** Select the waveform mode (GCONR.MODE);
- Step6.** Set the counting direction (only required when in sawtooth wave mode GCONR.MODE=0);
- Step7.** Set the capture input mode (PCNAR.CAPMDA=1 and PCNBR.CAPMDB=1);
- Step8.** Start the counter (GCONR.START=1);

- Step9.** Wait for the capture input condition to occur, then read the capture input value from the corresponding channel (GCMAR or GCMBR), or wait for the corresponding interrupt to be triggered.

#### 21.4.4 Buffer Transmission Action (Period Reference Value)

- Step1.** Set the required general period reference value (PERAR, PERBR, PERCR);
- Step2.** Set the single or double buffer transmission mode (BCONR.BSEP);
- Step3.** Set the buffer transmission time point (BCONR.BTRUP, BCONR.BTRDP, these two control bits are independent of each other and can be selected at the same time as the buffer transmission time point) (this setting is only valid in triangle wave mode and invalid in sawtooth wave mode);
- Step4.** Set the internal count clock frequency division (GCONR.CKDIV);
- Step5.** Set the waveform mode (GCONR.MODE);
- Step6.** Set the counting direction (only required in sawtooth wave mode when GCONR.MODE=0);
- Step7.** Set the buffer function as valid (BCONR.BENP=1).
- Step8.** Start the counter (GCONR.START=1);
- Step9.** Wait for the corresponding buffer transmission time point, and the buffer action occurs (PERBR->PERAR (when BCONR.BSEP=0), PERCR->PERBR->PERAR (when BCONR.BSEP=1) ).

#### 21.4.5 Buffer Transmission Action (General Compare Reference Value)

- Step1.** Set the required general compare reference value (GCMAR, GCMCR, GCMER, GCMBR, GCMDR, GCMFR);
- Step2.** Set the single or double buffer transmission mode for each channel (BCONR.BSEA, BCONR.BSEB);
- Step3.** Set the buffer transmission time point of each channel (BCONR.BTRUA, BCONR.BTRDA, BCONR.BTRUB, BCONR.BTRDB, the two control bits of each channel are independent of each other and can be selected at the same time as the buffer transmission time point) (this setting is only valid in triangle wave mode and invalid in sawtooth wave mode);
- Step4.** Set the internal count clock division (GCONR.CKDIV);
- Step5.** Set the waveform mode (GCONR.MODE);
- Step6.** Set the counting direction (only required in sawtooth wave mode when GCONR.MODE=0);
- Step7.** Set the buffer function of each channel to be valid (BCONR.BENA=1, BCONR.BENB=1);
- Step8.** Start the counter (GCONR.START=1);
- Step9.** Wait for the corresponding buffer transmission time point set for each channel, and the buffer action occurs (GCMCR->GCMAR (when BCONR.BSEA=0), GCMER->GCMCR->GCMAR (when BCONR.BSEA=1), GCMDR->GCMBR (when BCONR.BSEB=0), GCMFR->GCMDR->GCMBR (when BCONR.BSEB=1) ).

#### 21.4.6 Buffer Transmission Action (Special Compare Reference Value)

- Step1.** Set the required special compare reference value (SCMAR, SCMCR, SCMER, SCMBR, SCMDR, SCMFR);
- Step2.** Set the single or double buffer transmission mode for each channel (BCONR.BSESPA, BCONR.BSESPB);
- Step3.** Set the buffer transmission time point of each channel (BCONR.BTRUSPA, BCONR.BTRDSPA, BCONR.BTRUSPB, BCONR.BTRDSPB, the two control bits of each channel are independent of each other and can be selected at the same time as the buffer transmission time point) (this setting is only valid in triangle wave mode and invalid in sawtooth wave mode);

- Step4.** Set the internal count clock division (GCONR.CKDIV);
- Step5.** Set the waveform mode (GCONR.MODE);
- Step6.** Set the counting direction (only required in sawtooth wave mode when GCONR.MODE=0).
- Step7.** Set the buffer function of each channel to be valid (BCONR.BENSPA=1, BCONR.BENSPB=1);
- Step8.** Start the counter (GCONR.START=1);
- Step9.** Wait for the corresponding buffer transmission time point set for each channel, and the buffer action occurs (SCMCR->SCMAR (when BCONR.BESPA=0), SCMER->SCMCR->SCMAR (when BCONR.BESPA=1), SCMDR->SCMBR (when BCONR.BESPB=0), SCMFR->SCMDR->SCMBR (when BCONR.BESPB=1) ).

#### 21.4.7 Buffer Transmission Action (Dead Zone Reference Value)

- Step1.** Set the required dead time reference value(DTUAR, DTUBR, DTDAR, DTDBR);
- Step2.** Set the buffer transmission time point (DCONR.DTBTRU, DCONR.DTBTRD, these two control bits are independent of each other and can be selected at the same time as the buffer transmission time point) (this setting is only valid in triangle wave mode and invalid in sawtooth wave mode);
- Step3.** Set the internal count clock division (GCONR.CKDIV);
- Step4.** Set the waveform mode (GCONR.MODE);
- Step5.** Set the counting direction (only required in sawtooth wave mode when GCONR.MODE=0);
- Step6.** Set the buffer function to be enabled (DCONR.DTBENU=1, DCONR.DTBEND=1);
- Step7.** Set the hardware dead zone function to be enabled (DCONR.DTCEN=1);
- Step8.** Start the counter (GCONR.START=1);
- Step9.** Wait for the corresponding buffer transmission time point and the buffer action to occur (DTUBR->DTUAR, DTDBR->DTDAR).

#### 21.4.8 Synchronization Start Action (Software Mode)

- Step1.** Refer to steps 1 to 6 in the "Basic Counting and Interrupt Action" section to set each unit that needs to be started synchronously;
- Step2.** Synchronously start the counter (set the corresponding bit of the SSTAR register to 1, each unit corresponds to a register bit).

#### 21.4.9 Synchronization Start Action (Hardware Mode)

- Step1.** Set the general oeriod reference value (PERAR);
- Step2.** Set the required compare reference value, including the general compare reference value (GCMAR-GCMFR), the special compare reference value (SCMAR-SCMBR), etc.;
- Step3.** Set the required interrupt enable bit, including the count overflow interrupt (ICONR.INTENOVF), the count underflow interrupt (ICONR.INTENUF), the count match interrupt (ICONR.INTENA-F, ICONR.INTENSAU, ICONR.INTENSAD, ICONR.INTENSB, ICONR.INTENSBD), etc.;
- Step4.** Set the hardware start condition (select through HSTAR.HSTAx, x=8-31);
- Step5.** Set the hardware start enable (HSTAR.STAS=1);
- Step6.** Repeat the above steps 1-5 to set each unit that needs to be started synchronously (the setting of step 4 must be consistent in each unit that needs to be started synchronously);
- Step7.** Wait for the set trigger event to occur and confirm that the counters of each unit are started synchronously.

### 21.4.10 Quadrature Encoding Count Action (2-phase)

- Step1.** Set the General Period Reference Value (PERAR);
- Step2.** Set the required compare reference value, including the general compare reference value (GCMAR-GCMFR), the special compare reference value (SCMAR-SCMBR), etc.;
- Step3.** Set the required interrupt enable bit, including the count overflow interrupt (ICONR.INTENOVF), the count underflow interrupt (ICONR.INTENUDF), the count match interrupt (ICONR.INTENA-F, ICONR.INTENSAU, ICONR.INTENSAD, ICONR.INTENSBU, ICONR.INTENSBD), etc.;
- Step4.** Set the required hardware up-counting condition (selected by HCUPR.HCUPx, x=0-7);
- Step5.** Set the required hardware down-counting condition (selected by HCDOR.HCDOx, x=0-7);
- Step6.** Start the counter (GCONR.START=1);
- Step7.** Wait for the set quadrature encoding counting event to occur and confirm that the counter is counting normally.

### 21.4.11 Quadrature Encoding Count Action (3-phase)

- Step1.** Refer to steps 1 to 5 in the "Quadrature Encoding Count Action (2-phase)" section to set the position counting unit;
- Step2.** Set the hardware clearing condition of the position counting unit (selected by HCLRR.HCLRx, x=16-31);
- Step3.** Set the hardware clearing enable of the position counting unit (HCLRR.CLES=1);
- Step4.** Set the general period reference value (PERAR) of the revolution counting unit;
- Step5.** Set the compare reference value of the revolution counting unit, including the general compare reference value (GCMAR-GCMFR), the special compare reference value (SCMAR-SCMBR), etc.;
- Step6.** Set the interrupt enable bits required by the revolution counting unit, including count overflow interrupt (ICONR.INTENOVF), count underflow interrupt (ICONR.INTENUDF), count match interrupt (ICONR.INTENA-F, ICONR.INTENSAU, ICONR.INTENSAD, ICONR.INTENSBU, ICONR.INTENSBD), etc.;
- Step7.** Configure hardware count-up condition 1 for the revolution counter unit (ZIN-phase input) (Select via HCUPR.HCUPx, x=16-31. This setting event must be consistent with the event configured for the position counter unit in Step 2);
- Step8.** Configure hardware count-up condition 2 (The overflow event input of the position counting unit) (Select internal hardware trigger event 0 via HCUPR.HCUP8);
- Step9.** Set the hardware count-down condition (The underflow event input of the position counting unit) (Select internal hardware trigger event 1 via HCDOR.HCDO9);
- Step10.** Set the trigger source number in TMR6\_TRGSEL0 to the count overflow event of the position counting unit (for the register content, see the "Register-Timer6 Hardware Trigger Event Selection Register (TMR6\_TRGSELx) (x=0-3) " in the "Automatic Operation System (AOS) " chapter, and for the overflow event number, see the "Interrupt Controller (INTC) " chapter);
- Step11.** Set the trigger source number in TMR6\_TRGSEL1 to the count underflow event of the position counting unit (for the register content, see the "Register-Timer6 Hardware Trigger Event Selection Register (TMR6\_TRGSELx) (x=0-3) " in the "Automatic Operation System (AOS) " chapter, and for the overflow event number, see the "Interrupt Controller (INTC) " chapter);
- Step12.** Start the revolution counting unit counter (GCONR.START=1);
- Step13.** Start the position counting unit counter (GCONR.START=1);
- Step14.** Wait for the set AIN, BIN, ZIN phase counting events to occur and confirm that the counter is counting normally.

### 21.4.12 Single Channel PWM Output

Refer to the settings of steps 1 to 10 in the "[compare Output and Interrupt Action](#)" section (the output status of the two PWM channels TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB inside each unit can be set independently to form two independent single-channel PWM outputs).

### 21.4.13 Complementary PWM Output (Software Dead Zone)

- Step1.** Set the general period reference value (PERAR);
- Step2.** Set the general compare reference value A (GCMAR) and general compare reference value B (GCMBR);
- Step3.** Set the required interrupt enable bits, including count overflow interrupt (ICONR.INTENOVF), count underflow interrupt (ICONR.INTENUF), count match interrupt (ICONR.INTENA-B), etc.;
- Step4.** Set the port output states for different counter conditions (refer to Bit17-Bit0 of PCNAR and PCNBR for control settings. In conjunction with the values set in GCMAR and GCMBR, ensure that a complementary dead time is formed between the two PWM outputs);
- Step5.** Set the internal count clock division (GCONR.CKDIV);
- Step6.** Set the waveform mode to triangle wave mode (GCONR.MODE=1);
- Step7.** Set the comparison output mode (PCNAR.CAPMDA=0, PCNBR.CAPMDB=0);
- Step8.** Enable the outputs (PCNAR.OUTENA=1, PCNBR.OUTENB=1);
- Step9.** Start the counter (GCONR.START=1).

### 21.4.14 Complementary PWM Output (Hardware Dead Zone)

- Step1.** Set the general period reference value (PERAR);
- Step2.** Set the general compare reference value A (GCMAR), and the dead time reference value (DTUAR, DTDAR);
- Step3.** Set the required interrupt enable bits, including the counter overflow interrupt (ICONR.INTENOVF), counter underflow interrupt (ICONR.INTENUF), count match interrupts (ICONR.INTENA-B), and the dead-time error interrupt (ICONR.INTENDTE), etc.;
- Step4.** Set the port output states for different counter conditions (refer to Bit17-Bit0 of PCNAR and PCNBR for related control settings. In conjunction with the configured values of GCMAR, DTUAR, and DTDAR, ensure that a complementary dead time is formed between the two PWM outputs);
- Step5.** Set the internal count clock division (GCONR.CKDIV);
- Step6.** Set the waveform mode to triangle wave mode (GCONR.MODE=1);
- Step7.** Set the comparison output mode of each channel (PCNAR.CAPMDA=0, PCNBR.CAPMDB=0);
- Step8.** Set each channel output enable (PCNAR.OUTENA=1, PCNBR.OUTENB=1);
- Step9.** Set the hardware dead zone function to be enabled (DCONR.DTCEN=1);
- Step10.** Start the counter (GCONR.START=1).

### 21.4.15 EMB Monitoring and Interrupt Action

- Step1.** Refer to steps 1-8 in the "[Complementary PWM Output \(Software Dead Zone\)](#)" section or steps 1-9 in the "[Complementary PWM Output \(Hardware Dead Zone\)](#)" section to set the complementary PWM output action;
- Step2.** Set the PWM port state when an EMB event occurs (PCNAR.EMBCA, PCNBR.EMBCB) (select the appropriate protection state according to the system application);
- Step3.** Set the time point at which the PWM port resumes normal output after the EMB event becomes inactive (PCNAR.EMBRA, PCNBR.EMBRB);

- Step4.** Set the EMB event source input from the EMB module (PCNAR.EMBSA, PCNBR.EMBSB);
- Step5.** Set the relevant EMB module registers (including the EMB interrupt permission registers (EMB\_INTEN0-3), EMB control registers 1/2 (EMB\_CTL1/2\_0-3), and the EMB control PWM output release mode selection registers (EMB\_RLSSEL0-3), etc.);
- Step6.** Start the counter (GCONR.START=1), and the EMB module monitors the system status in real time.

## 21.5 Register Description

### 21.5.1 Register List

- Timer6\_1 base address: 0x40018000
- Timer6\_2 base address: 0x40018400
- Timer6\_3 base Address: 0x40018800
- Timer6\_4 base address: 0x40018C00
- Timer6\_5 base address: 0x40019000
- Timer6\_6 base address: 0x40019400
- Timer6\_7 base address: 0x40019800
- Timer6\_8 base address: 0x40019C00

#### Note

Timer6 is the name of the timer, and Timer6\_<t> (where <t>: 1-8) refers to the timer unit.

Table 21-4 Advanced Control Timer (Timer6) Register Offset

| Offset | Register   | Description                                | Width |
|--------|------------|--------------------------------------------|-------|

Timer6 common register base address: 0x40018300

Table 21-5 Timer6 Common Register Offset

| Offset | Register                   | Description                                          | Width |
|--------|----------------------------|------------------------------------------------------|-------|
| 0x00EC | <a href="#">TMR6_FCNT</a>  | Common Filter Control Register                       | 32    |
| 0x00F0 | <a href="#">TMR6_SSTAR</a> | Common Software Synchronous Start Control Register   | 32    |
| 0x00F4 | <a href="#">TMR6_SSTPR</a> | Common Software Synchronous Stop Control Register    | 32    |
| 0x00F8 | <a href="#">TMR6_SCLRR</a> | Common Software Synchronous Clear Control Register   | 32    |
| 0x00FC | <a href="#">TMR6_SUPDR</a> | Common Software Synchronous Refresh Control Register | 32    |

**Note**

- The bit widths of the general count value register, general refresh value register and reference registers of unit 1 to unit 4 are all 32 bits, and the reset values are different from those of unit 5 to unit 8. Among them, the reset value of the general count value register and the general refresh value register is 0x00000000; the reset value of each reference value register is 0xFFFFFFFF.
- Trigger Selection Registers (TMR6\_TRGSEL0-3) : These are 4 independent registers that are shared by all 8 Timer6 units..
- Software Synchronous Registers (TMR6\_SSTAR, TMR6\_SSTPR, TMR6\_SCLLR, TMR6\_SUPDR) : These are 4 independent registers that are shared by all 8 Timer6 units.
- Filter Control Register (TMR6\_FCNTNTR) : This is a single independent register shared by all 8 Timer6 units.

**Note**

The internal signal TMR6\_<t>\_XOR is the signal obtained by performing an XOR logic operation on TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB.

## 21.6 Precautions

- The CPU cannot write to the CNTER register when the counter is counting, and can only write to the CNTER register when the counter stops.
- When the corresponding buffer function is enabled, the interrupt and event outputs of GCMCR-GCMFR are disabled.
- When using the double-edge complementary symmetric PWM output function, users must calculate and set the relevant references and port output states in advance to ensure the output ports are in the expected state.
- When using the PTO function, if a value of 0 is written to TMR6\_PTNUMR, TMR6\_CNTER continues counting and the PTO output remains unchanged. When a non-zero value is subsequently written to TMR6\_PTNUMR, ABZ phase output will resume.
- When using the PTO function, the timing for writing TMR6\_PTNUMR/PTPERR must align with TMR6\_CNTER equaling TMR6\_GCMAR. It is recommended that TMR6\_GCMAR be set within 20% to 80% of TMR6\_PEAR (the algorithm period).
- In specific scenarios, multiple control events may target the counter simultaneously. In such cases, the priority order of CNTER behavior is determined according to the following table.

Table 21-90 CNTER Control Priority

| Timer Control Events                |                                     | CNTER Value                         | Priority |
|-------------------------------------|-------------------------------------|-------------------------------------|----------|
| CPU write to CNTER                  |                                     | CPU write value                     | High     |
| Update event (software or hardware) |                                     | Value from UPDAR                    | ↓        |
| Clear event (software or hardware)  | In hardware count or saw-tooth mode | 0 or PERAR based on count direction | ↓        |
|                                     | In triangular wave mode             | 0                                   | ↓        |
| Hardware counting                   |                                     | Normal counting value               | ↓        |
| Triangular wave mode counting       |                                     | Normal counting value               | ↓        |
| Sawtooth mode counting              |                                     | Normal counting value               | Low      |

- In specific scenarios, control events targeting the PWM port outputs may occur simultaneously. In such cases, the output change priority for the two ports (TMR6\_<t>\_PWMA and TMR6\_<t>\_PWMB) is defined separately as follows:

Table 21-91 PWMA Port Output Control Priority

| PWMA Port Output Control Events | Port State                   | Priority |
|---------------------------------|------------------------------|----------|
| EMB-triggered event occurs      | State defined by PCNAR.EMBCA | High     |
| Forced port output enabled      | State defined by PCNAR.FORCA | ↓        |
| At the start of counting        | State defined by PCNAR.STACA | ↓        |

| PWMA Port Output Control Events |             | Port State                    | Priority |
|---------------------------------|-------------|-------------------------------|----------|
| In sawtooth up-count            | CNTER=PERAR | State defined by PCNAR.OVFCA  | ↓        |
|                                 | CNTER=GCMAR | State defined by PCNAR.CMAUCA | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNAR.CMBUCA | ↓        |
| In sawtooth down-count          | CNTER=0     | State defined by PCNAR.UDFCA  | ↓        |
|                                 | CNTER=GCMAR | State defined by PCNAR.CMADCA | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNAR.CMBDCA | ↓        |
| In triangular up-count          | CNTER=GCMAR | State defined by PCNAR.CMAUCA | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNAR.CMBUCA | ↓        |
|                                 | CNTER=PERAR | State defined by PCNAR.OVFCA  | ↓        |
| In triangular down-count        | CNTER=GCMAR | State defined by PCNAR.CMADCA | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNAR.CMBDCA | ↓        |
|                                 | CNTER=0     | State defined by PCNAR.UDFCA  | ↓        |
| When counting stops             |             | State defined by PCNAR.STPCA  | Low      |

Table 21-92 PWMB Port Output Control Priority

| PWMB Port Output Control Events |             | Port State                    | Priority |
|---------------------------------|-------------|-------------------------------|----------|
| EMB-triggered event occurs      |             | State defined by PCNBR.EMBCEB | High     |
| Forced port output enabled      |             | State defined by PCNBR.FORCEB | ↓        |
| At the start of counting        |             | State defined by PCNBR.STACB  | ↓        |
| In sawtooth up-count            | CNTER=PERAR | State defined by PCNBR.OVFCEB | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNBR.CMBUCB | ↓        |
|                                 | CNTER=GCMAR | State defined by PCNBR.CMAUCB | ↓        |

| PWMB Port Output Control Events |             | Port State                    | Priority |
|---------------------------------|-------------|-------------------------------|----------|
| In sawtooth down-count          | CNTER=0     | State defined by PCNBR.UDFCB  | ↓        |
|                                 | CNTER=GCMBR | State defined by PCNBR.CMBDCB | ↓        |
|                                 | CNTER=GCMAR | State defined by PCNBR.CMADCB | ↓        |
| In triangular up-count          | CNTER=GCMBR | State defined by PCNBR.CMBUCB | ↓        |
|                                 | CNTER=GCMAR | State defined by PCNBR.CMAUCB | ↓        |

## 22 General Control Timer (Timer4)

### 22.1 Introduction

The General Control Timer 4 is a timer module designed for three-phase motor control, offering a variety of solutions for different three-phase motor control applications. It supports both triangular and sawtooth waveform modes, enabling the generation of various PWM waveforms. It also features buffer functionality and supports EMB control. 3 unit of Timer4 is carried in this product family.

### 22.2 Features

The following table outlines the basic functions and features of Timer4.

Table 22-1 Basic Functions and Features of Timer4

|                |                                             |
|----------------|---------------------------------------------|
| Waveform mode  | Sawtooth wave, triangle wave                |
| Basic function | Up/Down-counting direction                  |
|                | Buffer function                             |
|                | General PWM output                          |
|                | General compare match event                 |
|                | Overflow/Underflow/Reload count match event |
|                | Special compare match event                 |
|                | Software-synchronized counter start         |
|                | EMB control                                 |
| Interrupt type | General compare match interrupt             |
|                | Count period match interrupt                |
|                | Reload count match interrupt                |

## 22.3 Functional Description

### 22.3.1 Timer4 Block Diagram

The figure below describes the basic architecture of the general control timer Timer4. In the diagram, the symbol "<t>" denotes the unit number, which ranges from 1-3. In the remainder of this section, "<t>" will consistently refer to the unit number and will not be further explained.

Figure 22-1 Timer4 Basic Block Diagram

The following table lists the input and output ports of Timer4.

Table 22-2 Timer4 Port List

| Port Name     | Direction | Function                        |
|---------------|-----------|---------------------------------|
| TMR4_<t>_CLK  | Input     | Count clock input port          |
| TMR4_<t>_PCT  | Output    | PWM periodic output monitoring  |
| TMR4_<t>_ADSM | Output    | Special event output monitoring |

| Port Name    | Direction | Function        |
|--------------|-----------|-----------------|
| TMR4_<t>_OUH | Output    | PWM output port |
| TMR4_<t>_OUL |           |                 |
| TMR4_<t>_OVH |           |                 |
| TMR4_<t>_OVL |           |                 |
| TMR4_<t>_OWH |           |                 |
| TMR4_<t>_OWL |           |                 |

## 22.3.2 Basic Actions

### 22.3.2.1 Waveform Mode

Timer4 has two basic counting waveform modes, sawtooth wave mode and triangle wave mode. The two waveform modes can be implemented based on the setting of CCSR.MODE.

Figure 22-2 Timer4 Sawtooth Waveform

Figure 22-3 Timer4 Triangle Waveform

### 22.3.2.2 Counting Action

- The sawtooth wave counting operation and control process are shown in the figure below:

Figure 22-4 Timer4 Sawtooth Wave Mode Counting Action

1. Setting mode `CCSR.MODE=0`.
  2. Set the count peak CPSR register.
  3. By writing `CCSR.STOP=0` and `CCSR.CLEAR=1`, the counter count value (CNTR) is initialized to 0x0000 and the counting operation is started. The counter value starts counting up from 0x0000. When it reaches the peak value (CPSR), the count value returns to 0x0000, and this operation is repeated in sequence.
  4. Counting period =  $(\text{CPSR} + 1) \times \text{counting clock period}$ .
  5. During the counting process, writing `CCSR.STOP=0` and `CCSR.CLEAR=1` can initialize the counting value to 0x0000 and continue counting operation.
  6. During the counting process, writing `CCSR.STOP=1` and `CCSR.CLEAR=1` can initialize the count value to 0x0000 and stop the counting operation.
- The triangle wave counting operation and control process are shown in the figure below:

Figure 22-5 Timer4 Triangle Wave Mode Counting Action

1. Setting mode `CCSR.MODE=1`.
2. Set the count peak CPSR register.
3. By writing `CCSR.STOP=0` and `CCSR.CLEAR=1`, the counter count value (CNTR) is initialized to 0x0000 and the counting operation is started. The counter value starts counting up from 0x0000 and counts up before reaching the counting peak value; when the peak value (CPSR) is reached, the counter starts counting down until the count value returns to 0x0000; then the counting operation is repeated again, and this operation is repeated in sequence.
4. Counting period =  $\text{CPSR} \times 2 \times \text{counting clock period}$ .
5. During the counting process, writing `CCSR.STOP=0` and `CCSR.CLEAR=1` can initialize the count value to 0x0000 and restart the increment counting operation, and then repeat the above operation.

6. During the counting process, writing `CCSR.STOP=1` and `CCSR.CLEAR=1` can initialize the count value to 0x0000 and stop the counting operation.

### 22.3.2.3 Compare Output

The compare output function consists of universal comparators U, V, and W. The general comparator includes the compare reference register (`TMR4_OCCR`), the general control status register (`TMR4_OCSR`), the general extension control register (`TMR4_OCER`), and the general mode control register (`TMR4_OCMR`). The general comparator outputs an internal signal, which outputs a high or low level or PWM according to the configuration of the above registers.

Table 22-3 Internal Signal of General Comparator Output

| General Compa-rator   | Internal Signal | Description                                                                                                                                                                                                                                                                   |
|-----------------------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| General Compa-rator U | in_opuh         | When <code>OCSRu.OCEH=0</code> , the output high or low level is specified by <code>OCSRu.OCPh</code> ;<br>When <code>OCSRu.OCEH=1</code> , the PWM output is configured by the relevant bits of registers <code>OCCRuH</code> , <code>OCMRuH</code> and <code>OCERu</code> ; |

|                       | in_opvl         | When <code>OCSRv.OCEL=0</code> , the output high or low level is specified by <code>OCSRv.OCPL</code> ;<br>When <code>OCSRv.OCEL=1</code> , the PWM output is configured by the relevant bits of registers <code>OCCRvL</code> , <code>OCMRvL</code> and <code>OCERv</code> ; |
| General Compa-rator W | in_opwh         | When <code>OCSRw.OCEH=0</code> , the output high or low level is specified by <code>OCSRw.OCPh</code> ;<br>When <code>OCSRw.OCEH=1</code> , the PWM output is configured by the relevant bits of registers <code>OCCRwH</code> , <code>OCMRwH</code> and <code>OCERw</code> ; |
|                       | in_opwl         | When <code>OCSRw.OCEL=0</code> , the output high or low level is specified by <code>OCSRw.OCPL</code> ;<br>When <code>OCSRw.OCEL=1</code> , the PWM output is configured by the relevant bits of registers <code>OCCRwL</code> , <code>OCMRwL</code> and <code>OCERw</code> ; |

- The figure below is an example of the waveform output of the comparison output module in sawtooth counting mode.

Figure 22-6 Sawtooth Mode Waveform Output Example

- The figure below is an example of the waveform output of the comparison output module in triangle wave counting mode.

Figure 22-7 Triangular Wave Mode Waveform Output Example

### 22.3.3 Buffer Function

The Timer4 module provides buffer functionality for the CPSR Register, the OCCR Register, the OCMR Register, the SCCR Register, and the SCMR Register.

### 22.3.3.1 Count Period Set Register Buffer Function

The CPSR Register supports buffer function. When a peak count value is written, it is first stored in the buffer register. The data is transferred from the buffer register to the CPSR register under the following conditions:

1. When the buffer function is disabled (CCSR.BUFEN=0), the written data is immediately transferred from the buffer register to the CPSR register.
2. When the buffer function is enabled (CCSR.BUFEN=1), the data is transferred from the buffer register to the CPSR register either when the counter is stopped (CCSR.STOP=1) or when the counter value reaches 0x0000.

#### Notice

When reading from the CPSR, the value read is not from the buffer register but from the CPSR register itself. If the buffer function is enabled, the value read before the transfer is completed is not the most recently written value, but the previously loaded value of CPSR.

- When the sawtooth wave mode is on and the buffer function is disabled, modify the operation of the count peak CPSR:

CCSR.BUFEN=0

Figure 22-8 Modify Sawtooth Count Period When the Buffer is disabled

#### Notice

When the buffer function is disabled, the written data is immediately transferred from the buffer register to the CPSR register, and the counting period changes immediately after the write operation is completed. In this case, if the written value is smaller than the current counter value, the counter will continue incrementing until it reaches 0xFFFF. Therefore, special caution is required in such scenarios.

- When the sawtooth wave mode is on and the buffer function is enabled, modify the operation of the count peak CPSR:

Figure 22-9 Modify Sawtooth Wave Count Period when Buffer is Enabled

When the buffer function is enabled, the written data is transferred from the buffer register to the CPSR register when the counter stops or when the counter value is "0x0000".

- When the triangle wave mode is on and the buffer function is enabled, modify the operation of the count peak CPSR:

Figure 22-10 Modify Triangular Wave Count Period when Buffer is Enabled

In triangle wave counting mode, when the buffer function is enabled, the data written to the buffer register is transferred to the CPSR register when the counter stops or the next counter value is "0x0000." The change in the counter period occurs at the start of the next counter period after the write operation is completed.

### 22.3.3.2 General Compare Register Buffer Function

The general compare reference register (OCCR) and the general mode control register (OCMR) both have buffer register functions. When the buffer function is enabled, the data is loaded into the OCCR and OCMR registers at the specified transmission time. The OCCR buffer function is used to synchronize the change of the comparison value during the counting process, while the OCMR buffer function is used to synchronize the change of the internal PWM output at the counting overflow point (sawtooth wave), valley point, or peak point (triangle wave).

1. When the link transmission of output comparison with the counter period interval response function is disabled, the buffer value is loaded into the register at the set counting state. In this case, the loading process is independent of the counter period interval counter.

The figure below shows the waveform (x=L or H) when the general output compare OCCR buffer function is enabled, the counter is loaded at zero value (OCER.CxBUFEN=0b01), and the counter period interval response link is disabled (OCER.LMCx=0).

**Figure 22-11 OCCR Buffer Data Transmission (Period Interval Response Link Disabled)**

The upper part of the figure is a global schematic diagram, and the lower part is an enlarged view of the transmission operation.

The counter is in triangle wave counting mode, and the underflow interrupt is triggered at the flag ▲ (valley point). At ▼, the CPU rewrites the OCCR register and the data written is stored in the OCCR buffer register. After that, when the counter count is 0x0000, the data loading operation is performed, from the buffer register to the OCCR register, and the interrupt flag IRQZF is generated.

At Δ, the output comparison is based on the OCCR register value and counter value matching event, changing the PWM output and setting the OCSR.OCFx bit (x=L or H). After the ★ point (counter value=0x0000), the port output control operates based on the new OCCR data. Before the ★ point, the operation is based on the original OCCR data.

The figure illustrates the transmission operation of the OCCR buffer register at the counting valley point, and the buffer transfer operation of the OCMR buffer register is similar; similarly, the transmission operation at the counting peak point is also similar. New data becomes active immediately after the transmission time (newly written data will control the PWM output and set the interrupt flag).

2. **When the counter period interval response link is enabled, the buffer register transfer operation for the buffer value is executed when the counter is in the set counting state and the count value of the period interval counter is 0.**

The figure below shows the waveform (x=L or H) when the general output compare OCCR buffer function is enabled, the counter is loaded at zero value (OCER.CxBUFEN=0b01), and the counter period interval response link is enabled (OCER.LMCx=1).

Figure 22-12 OCCR Buffer Data Transmission (Period Interval Response Link Enabled)

The counter is in triangle wave counting mode, and the period interval counter (CVPR.ZIC) counts down from 2 to 0. The underflow interrupt is triggered at the flag ▲ (valley point). At ▼, the CPU rewrites the OCCR register, and the written data is stored in the OCCR buffer register. After that, when the counter count value is 0x0000 and the period interval counter (CVPR.ZIC) is 0, the data is loaded from the buffer register to the OCCR register, and the interrupt flag IRQZF is generated.

The figure shows the OCCR buffer register transfer operation at the counting valley point, and the OCMR buffer register transfer operation is similar. Similarly, the transfer operation at the counting peak is similar. The new data takes effect immediately after the transmission time (the new write data will control the PWM output and interrupt flag).

When using the channel link operation mode, enabling both the OCCRuh and OCCRul buffer functions can generate a variety of different PWM output waveforms. As shown in the figure below, while the output compare registers OCCRuh and OCCRul remain unchanged, changing the OCMR register value will make in\_opul output different waveform signals.

Figure 22-13 Output compare Buffer Data Transfer (OCMR Buffer Enabled)

### 22.3.3.3 Special Compare Register Buffer Function

The special compare control register (SCCR) and the special control mode register (SCMR) both have buffer function registers. When the buffer function is enabled, the values written by the CPU to the SCCR and SCMR buffer registers are loaded into the SCCR and SCMR registers at the set counter state.

1. When the counter period interval response link transmission is disabled, the buffer transmission operation is solely related to the counter state and is not affected by the counter period interval counter.

The following figure illustrates the operation when the register buffer function is enabled, the counter period interval response link transmission is disabled (SCSR.LMC=0), and the counter is at zero value (SCSR.BUFEN=0b01), transferring data to the SCCR and SCMR registers.

**Figure 22-14 SCCR Buffer Transmission Operation (Period Interval Response Link Transmission Disabled)**

The upper part of the figure is a global schematic diagram, and the lower part is a local enlarged diagram of the Buffer register transfer operation.

The counter is in triangle wave counting mode, and the underflow interrupt is triggered at the flag ▲ (valley point). At ▼, the CPU rewrites the SCCR register and the data written is stored in the SCCR buffer register. Afterwards, when the counter count value is 0x0000, the data loading operation is performed, and the data is transferred from the buffer register to the SCCR register, and the interrupt flag IRQZF is generated at the same time.

At time △, a comparison operation is performed based on the configured value in the SCCR register and the counter value. After time ★ (when the counter value equals 0x0000), the special event output signal operates according to the new SCCR data. Before the ★ point, the operation is based on the original SCCR data.

The figure illustrates the transmission operation of the SCCR buffer register at the counting valley point, and the buffer transfer operation of the SCMR buffer register is similar; similarly, the transmission operation at the counting peak point is also similar. The new data takes effect immediately after the transmission moment (the newly written data will set the special event output signal and interrupt flag).

2. When the counter period interval response link is enabled, the buffer register transfer operation is executed when the buffer value is in the set counting state and the count value of the period interval counter is 0.

The following figure shows the schematic diagram of enabling the SCCR buffer function, loading the counter at zero value (SCSR.BUFEN=0b01), and enabling the counter periodic interval response link transmission (SCSR.LMC=1).

Figure 22-15 SCCR Buffer Transmission Operation (when Periodic Interval Response Link Transmission Enabled)

The counter is in triangle wave counting mode, and the period interval counter (CVPR.ZIC) counts down from 2 to 0. The underflow interrupt is triggered at the flag ▲ (valley point). At ▼, the CPU rewrites the SCCR register and the data written is stored in the SCCR buffer register. After the counter value reaches 0x0000 and the period interval counter (CVPR.ZIC) is 0, the data load operation occurs, and the data is transferred from the buffer register to the SCCR register, triggering the interrupt flag IRQZF.

## 22.3.4 General PWM Output

### 22.3.4.1 Overview

When OCCR\*h, OCCR\*l, OCMR\*h, OCMR\*l, PSCR.OE\*H, PSCR.OE\*L, PDAR\*, PDBR\*, PSCR.OS\*H, PSCR.OS\*L, and OCER\* are mentioned later in this section, the wildcard character "\*" represents u, v, w; when referring to internal output signals in\_op\*h, in\_op\*l, the wildcard character "\*" represents u, v, w; when referring to ports TMR4\_<t>\_O\*H, TMR4\_<t>\_O\*L, the wildcard character "\*" represents U, V, W.

The port output control (U, V, W) function controls the output of the internal signal of the general comparator to the external ports TMR4\_<t>\_O\*H and TMR4\_<t>\_O\*L. The port output control includes the TMR4\_POCSR register, TMR4\_PSCR register, TMR4\_PFSR register, TMR4\_PDA<B>R register, and TMR4\_RCSR register.

The corresponding relationship between the internal signal of the general comparator output and the port output control is shown in the following table.

Table 22-4 Corresponding Relationship Between Internal Signal of General Comparator Output and Port Output Control

| General Comparator   | General Comparator Internal Signals | Port Output Control   |
|----------------------|-------------------------------------|-----------------------|
| General Comparator U | in_opuh                             | Port Output Control U |
|                      | in_opul                             |                       |
| General Comparator V | in_opvh                             | Port Output Control V |
|                      | in_opvl                             |                       |
| General Comparator W | in_opwh                             | Port Output Control W |
|                      | in_opwl                             |                       |

### 22.3.4.2 Independent PWM Output

In the pass-through mode (POCR.PWMMD=0b00), the references of OCCR\*h and OCCR\*l and the port output states of OCMR\*h and OCMR\*l are set respectively to achieve different PWM outputs. At this time, the PWM output of each port is controlled independently. Before using the independent PWM output

mode, you need to set the MOE, OE\*H, OE\*L bits (PSCR register) to enable the output of Timer4. For detailed description, please refer to "[PWM Status Control Register \(TMR4\\_PSCR\)](#)". The following two figures are examples of independent PWM output under sawtooth wave and triangle wave of unit 1.

Figure 22-16 Sawtooth Independent PWM Output Example

Figure 22-17 Triangle Independent PWM Output Example

#### Note

The pass-through mode means that the internal output signal (in\_op\*h, in\_op\*i) generated by the comparison match of the value of the general compare reference register (OCCR\*h, OCCR\*i) is directly output to the corresponding port (TMR4\_<t>\_O\*h, TMR4\_<t>\_O\*L).

### 22.3.4.3 Extended PWM Output

In pass-through mode (POCR.PWMMD=0b00), the port output status of TMR4\_<t>\_O\*L can also be determined by the extension bit (Bit32-16) in the OCMR\*i register. The setting of this extension bit is related to the OCCR\*h reference, thereby realizing extended PWM output on the TMR4\_<t>\_O\*L port. Before using the extended PWM output mode, you need to set the MOE, OE\*H, OE\*L bits (PSCR register) to enable the output of Timer4. For detailed description, please refer to the "[PWM Status Control Register](#)".

(TMR4\_PSCR)". The figure below shows the PWM output of TMR4\_<t>\_OUH and TMR4\_<t>\_OUL ports in this mode.

Figure 22-18 Sawtooth Wave Extended PWM Output

#### Note

In independent PWM output mode, the port status of TMR4\_<t>\_O\*L is determined by Bit15-Bit4 of the OCMRxl register and is only related to the OCCR\*I reference.

### 22.3.4.4 Complementary PWM Output

#### Software Setting for Complementary PWM Output

In the pass-through mode (POCR.PWMMD=0b00), directly set the OCCR\*h and OCCR\*l references to realize a pair of complementary PWM waveforms output to the port. The same setting of 3 groups of ports can realize 3-phase complementary PWM output.

Figure 22-19 Software Implementation of Complementary PWM Output

### Hardware Implementation of Complementary PWM Output

In the dead-zone generator mode (POCR.PWMMD=0b01), the internal output signal (in\_op\*I) generated by a comparison match of the general compare control register (OCCR\*I) and the set values in the PWM dead-zone control registers (PDAR/PDBR) are used to generate complementary PWM output through hardware, with timing offsets.

In this mode, the polarity of the output of the TMR4\_<t>\_O\*H port is the same as that of in\_op\*I, and the polarity of the output of the TMR4\_<t>\_O\*L port is opposite to that of in\_op\*I. The figure below is an example of complementary PWM output in dead-zone timer mode.

If the rising edge of in\_op\*I is detected, the TMR4\_<t>\_O\*L output becomes low level, and the dead zone counter loads the set value of the PDBR\* register and starts counting down. When the count value becomes 0x0000, the counter stops and TMR4\_<t>\_O\*H outputs high level; If the falling edge of in\_op\*I is detected, the TMR4\_<t>\_O\*H output becomes low level, and the dead zone counter loads the set value of the PDAR\* register and starts counting down. When the count value becomes 0x0000, the counter stops and makes TMR4\_<t>\_O\*L output high level.

By setting the PWM dead zone control registers PDAR and PDBR, the dead zone time of output rise and fall changes can be set accordingly.

Figure 22-20 Complementary PWM Output in Dead-Zone Generator Mode

When the high-level pulse width of in\_op\*I is less than the dead time set by PDBR, only the TMR4\_<t>\_O\*L output becomes low level. The condition for the TMR4\_<t>\_O\*L output level to become

high is when the dead time set by the PDAR register has passed after the falling edge of in\_op\*I. In this case, the TMR4\_<t>\_O\*H output will continue to remain at a low level.

When the low level pulse width of in\_op\*I is less than the dead time set by PDBR, only the TMR4\_<t>\_O\*H output becomes low level. The condition for the TMR4\_<t>\_O\*H output level to become high is after the dead time set by the PDBR register after the rising edge of in\_op\*I. In this case, the TMR4\_<t>\_O\*L output will continue to remain at a low level. As shown in the figure below.

Figure 22-21 Waveform Output in Dead-Zone Timer Mode with Pulse Width Anomalies

Based on the hardware implementation of dead-zone output, pulse width monitoring can also be applied to the internal compare match signal (in\_op\*I), enabling filtering control of the in\_op\*I signal. This method, where the in\_op\*I signal undergoes pulse width filtering, is called the Dead-Zone Counter Filter Mode (POCR.PWMMD=0b10).

In the Dead-Zone Counter Filter Mode, the filter width is determined by the value set in the PFSRn register. When the pulse width of in\_op\*I exceeds the time set in the PFSRn register, the filter counter will delay the in\_op\*I signal by the time set in PFSRn before outputting it. The output will then follow the dead-zone timer mode to generate complementary PWM signals.

If the rising edge of the signal in\_op\*I is detected, the filter counter loads the PFSR register value and starts measuring the high level width of in\_op\*I. When the high level pulse width of in\_op\*I is greater than the time set by the register PFSR, after the time set by PFSR, the TMR4\_<t>\_O\*L output becomes low level, and the dead zone counter loads the set value of the PDBR register and starts counting down. When the count value becomes 0x0000, the counter stops and makes TMR4\_<t>\_O\*H output high level. If the falling edge of the signal in\_op\*I is detected, the filter counter loads the PFSR register value and starts to measure the low-level width of in\_op\*I. When the low-level pulse width of in\_op\*I is greater than the time set by the register PFSR, after PFSR After the set time, the TMR4\_<t>\_O\*H output becomes low level, and the dead zone counter loads the set value of the PDAR register and starts counting down. When the count value becomes 0x0000, the counter stops and makes TMR4\_<t>\_O\*L output

high level. When the level pulse width of  $\text{in\_op}^*l$  is less than the time set by PFSR register, the outputs  $\text{TMR4\_}<t>\_O^*H$  and  $\text{TMR4\_}<t>\_O^*L$  will remain unchanged.

The following figure shows an example of complementary PWM output in dead-zone counter filter mode.

Figure 22-22 Complementary PWM Output in Dead-Zone Timer Filter Mode

#### Note

Before using software or hardware complementary PWM output mode, you need to set the MOE, OE\*H, OE\*L bits (PSCR register) to enable the output of Timer4. For detailed description, please refer to the "[PWM Status Control Register \(TMR4\\_PSCR\)](#)".

### 22.3.5 Periodic Interval Response

The underflow interrupt mask counter is used to reduce (mask) the number of times the underflow flag (CCSR.IRQZF) is set. The underflow interrupt mask counter (CVPR.ZIC) operates as a down counter and is loaded with the value set by CVPR.ZIM at the beginning. When CVPR.ZIC=0, the underflow flag (CCSR.IRQZF) is set to 1.

The overflow interrupt mask counter is used to reduce (mask) the number of times the overflow flag (CCSR.IRQPF) is set. The overflow interrupt mask counter (CVPR.PIC) operates as a down counter and is loaded with the value set by CVPR.PIM at the beginning. When CVPR.PIC=0, the overflow flag (CCSR.IRQPF) is set to 1.

The figure below is the setting timing diagram of IRQZF and IRQPF in periodic interval response.

### Figure 22-23 Periodic Interval Response Timing Diagram

- When the counter is stopped, write the initialization values of CVPR.ZIM and CVPR.PIM, and the initial values are immediately reflected in the internal counters (CVPR.ZIC, CVPR.PIC).
- Initialize and start the counter (STOP=0 and CLEAR=1). The counter starts counting up from zero after the bus is reset or CLEAR=1 is initialized from software. At this moment, the CCSR.IRQZF flag is not set immediately. After that, whenever the count value of the interrupt mask counter is 0x0000 and the count value of the counter is 0x0000 and CPSR, the flag ▲ is the moment when CCSR.IRQZF or CCSR.IRQPF is set.
- When the counter is running, if CVPR.ZIM and CVPR.PIM are written, the set value will not be immediately reflected in the interrupt mask counter (CVPR.ZIC and CVPR.PIC). If a soft reset (CLEAR=1) is written, the written CVPR.ZIM and CVPR.PIM values will be immediately loaded as the initial values of the interrupt mask counter.

The compare match event (special event output) of the SCCRM register also has a period interval response function. The figure below shows the periodic interval response output of the special event output signal.

Figure 22-24 Special Event Output Signal Periodic Interval Response Output

The counter is in triangle wave counting mode, and the underflow interrupt mask counter (CVPR.ZIC) counts down from 2-0. An underflow interrupt is generated at time ▲.

At time ▼1, value1 is written to the SCCRu buffer register. Meanwhile, MZCE=1, MPCE=0, AMC=0001 are written to the SCMRu buffer register. After that, the buffer registers SCCRu and SCMRu transfer operations are performed at time ▲. Because MZCE=1 and AMC=1 and the count value=SCCRu=Value1, at time Δ1, the special event output signal is set.

At time ▼2, value2 is written to the SCCRu buffer register. Meanwhile, MZCE=1, MPCE=0, AMC=0000 are written to the SCMRu buffer register. After that, the buffer registers SCCRu and SCMRu transfer operations are performed at time ▲. Because MZCE=1 and AMC=0 and the count value=SCCRu=Value2, at time Δ2, the special event output signal is set.

### 22.3.6 EMB Control

Each Timer 4 unit has an output inactive event interface connected to the EMB event output from the EMB module. The abnormal condition event selected on this interface can be set from the EMB side (refer to the "Emergency Brake Module (EMB) " chapter).

During the normal output period of the 3 groups of PWM ports in each unit, if the EMB abnormal event from the EMB is detected, the PSCR.MOE bit is cleared asynchronously by hardware, and the output state of each PWM port changes to the preset state. According to the settings of PSCR.OS\*H and PSCR.OS\*L, the preset port state can be output high impedance, output low level or output high level.

For example, if PSCR.OSUH=0b01 is set, an EMB event is generated during the normal output period of the TMR4\_<t>\_OUH port of Timer4, and the output on the TMR4\_<t>\_OUH port changes to a high impedance state.

After the EMB exception event is cleared, if PSCR.AOE=1 at this time, PSCR.MOE will be automatically set by hardware, and then the PWM port will resume normal output; if PSCR.AOE=0 at this time, PSCR.MOE needs to be set by software to restore the PWM port to normal output.

It should be noted that the asynchronous signal of MOE is used to control the PWM output enable in hardware. When the value of MOE changes, it is necessary to wait for several clock periods to read the actual value on the bus (it is necessary to wait for 4 Timer4 bus clock periods after the EMB abnormal

event occurs, and it is necessary to wait for 6 Timer4 bus clock periods after the EMB abnormal event is resolved).

For detailed operation methods of EMB, please refer to the relevant description of the "Emergency Brake Module (EMB)" chapter.

### 22.3.7 Monitoring Output

Each Timer4 unit has a PWM period output monitoring port TMR4\_<t>\_PCT and a special event output monitoring port TMR4\_<t>\_ADSM. These monitoring ports are output to the outside, and users can flexibly control the application system based on the port change information.

The PWM period output monitoring port TMR4\_<t>\_PCT is used to monitor the current counter count state. In the triangle wave mode, each time the count reaches the peak or trough, a flip occurs on the monitoring port TMR4\_<t>\_PCT. The following figure is an example of the counting direction signal.

Figure 22-25 PWM Period Output Monitoring Example

The special event output monitoring port TMR4\_<t>\_ADSM can be used to monitor the special comparison event of the internal counter. Select the special comparison output channel that needs to be monitored through the SCER.EVTRS bit. When the compare reference on this channel and the counter produce a comparison match, the monitoring port TMR4\_<t>\_ADSM will be set (the output is high); when the counter count on this channel returns to zero (the sawtooth wave overflows and the triangle wave counts to the trough), the monitoring port TMR4\_<t>\_ADSM will be reset (the output is low).

It should be noted that when the configuration register TMR4\_SCSRm enables both up-counting EVT and down-counting EVT (TMR4\_SCSRm.UEN=1 and TMR4\_SCSRm.DEN=1), the synchronization signal output to the external port is only active for up-counting EVT.

The following figure shows an example of the synchronized signal output to the port in comparison start mode (SCSRm.EVTMS=0). After the EVT is enable in up-counting mode, TMR4\_<t>\_ADSM is set. After the counter underflows, TMR4\_<t>\_ADSM is cleared.

Figure 22-26 Special Event Output TMR4\_&lt;t&gt;\_ADSM Timing in Compare Start Mode

### 22.3.8 Synchronous Starting

This product is equipped with three units of Timer4, which can realize synchronous software startup. Unit 1 can start units 2 and 3 synchronously.

When the CCSR.SYNST bit in the synchronized unit m (m=2, 3) is set to 1, the synchronized start function of the unit is enabled. At this time, if the software sets the CCSR.STOP bit of unit 1 to 0, the counter of synchronized unit m starts counting synchronously with the counter of unit 1.

In addition, the product is equipped with a count synchronization enable register TMR\_SYNENRx (x=1-2) to synchronously start all the timers (including Timer0, Timer2, Timer4, Timer6, TimerA) carried by the product. For usage and register description, please refer to the description in the "General Timer (Timer0) " section. Please do not use this function when this timer is counting asynchronously.

### 22.3.9 Interrupt and Event

#### General Count Compare Match Interrupt and Event

There are a total of 6 general compare reference registers (OCCRm), each of which can generate a compare match enable signal when matched with the counter value. When the count compare matches, the OCSRn.OCFH and OCSRn.OCFL bits in the common control status register (OCSRn) will be set to 1 respectively. At this time, if OCSRn.OCIEH and OCSRn.OCIEL are set to enable interrupts, the corresponding interrupt request (TMR4\_<t>\_GCMmn, m=U, V, W; n=H, L) will also be triggered.

The general count compare match event can be used to trigger other modules. For the event number, please refer to the "Interrupt Event List" in the "Interrupt Controller (INTC) " chapter.

#### Count Period Match Interrupt and Event

When the sawtooth wave counts up to the overflow point, the triangle wave counts to the valley point, or the triangle wave counts to the peak point, the CCSR.IRQPF or CCSR.IRQZF bit will be set to 1. At this time, if the CCSR.IRQPEN or CCSR.IRQZEN bit is set to enable interrupt, the count period match interrupt (TMR4\_<t>\_GOVF and TMR4\_<t>\_GUDF) can be triggered at the corresponding time point.

The count period match event can be used to trigger other modules. For event numbers, refer to the 'Interrupt Event List' in the 'Interrupt Controller (INTC) ' chapter.

#### Reload Count Match Interrupt and Event

When the reload function is enabled, TMR4\_PFSRn serves as the period count value for the reload timer. When counting is enabled, the counter is reloaded with the value in TMR4\_PFSRn and performs

a decrement operation. After completing one period, a reload count interrupt request is generated, the RCSR.RTIFU, RCSR.RTIFV, RCSR.RTIFW bits are set to 1, respectively. If the interrupt masks RCSR.RTIDU, RCSR.RTIDV, RCSR.RTIDW are disabled, the corresponding reload compare match interrupt requests (TMR4\_<t>\_RLOm, where m=U, V, W) will be triggered.

Reload compare match events can be used to trigger other modules; for the event numbers, refer to the "Interrupt Event List" in the "Interrupt Controller (INTC) " chapter.

### Special Compare Match Events

The 6 special compare reference registers (SCCRm) of Timer4 generate 6 special event output signals corresponding to them, which can be used to select and trigger other modules, such as starting the ADC.

During the clock counting process, if the special compare reference (SCCRm) has a count comparison match event (TMR4\_<t>\_SCM0-5), a corresponding enable request signal will be generated. This request signal can be assigned to any EVT event output signal (configured via the SCSR.EVTOS bit) to trigger other modules.

The output of this event request signal can be configured for either Comparison Start Mode or Delay Start Mode. In comparison start mode (SCSR.EVTMS=0), after the count compare match event of SCCR is generated, the special event output signal is directly output; in delay start mode (SCSR.EVTMS=1), after the count compare match event of OCCR\*h or OCCR\*l (selected by SCSR.EVTDS bit) is generated, the special event output signal is output after the reference period time set by SCCR. The figure below illustrates an example of the event request signal output in Delay Start Mode.

Special compare match events can be used to trigger other modules. For event numbers, please refer to the "Interrupt Event List" in the "Interrupt Controller (INTC) " chapter.

Figure 22-27 Output Timing of Special Event Output Signal in Delayed Start Mode

#### Note

During delay counting, if another match event between OCCR and the counter occurs, the delay counter reloads and begins decrementing again. Therefore, if the interval between OCCR match events is shorter than the delay period defined by SCCR, the special event output request signal may never be generated.

## 22.4 Register Description

### 22.4.1 Register List

- Timer4\_1 base address: 0x40038000
- Timer4\_2 base address: 0x40038400
- Timer4\_3 base address: 0x40038800

#### Note

Timer4 is the name of the timer, and Timer4\_<t> (<t>: 1-3) is the timer unit.

Table 22-5 General Control Timer (Timer4) Register Offset

| Offset | Register    | Description                           | Width |
|--------|-------------|---------------------------------------|-------|
| 0x0046 | TMR4_CNTR   | Count Value Register                  | 16    |
| 0x0042 | TMR4_CPSR   | Period Reference Register             | 16    |

**Notice**

- When reading data from this address area, the value read is not from the buffer register, but from the OCMR register.
- TMR4\_<t>\_O\*L can be determined by OCCR\*I and the count value of the counter (independent operation mode), or OCCR\*h and the count value of the counter and OCCR\*I and the count value of the counter (linked operation mode). Write the same 12-bit value to Bit[31:20] and Bit[15:4] of register OCMR\*I, and write 0b0000 to OCMR\*I[19:16]. At this time, the in\_op\*I output will not be affected by OCCR\*h, but only by OCCR\*I. Independent operation mode: channel\*H is configured by OCCR\*h, and channel\*L is configured by OCCR\*I. If the independent operation mode does not meet the above conditions, it is the linked operation mode: channel\*L output is affected by both OCCR\*h and OCCR\*I.
- When the following two conditions are met, it is also considered to meet the conditions set by OCMR\*h.OPPKH:
  - CCSR.MODE=1 && Count overflow && OCCR\*h=0xFFFF
  - OCER\*.MCECH=1 && Count overflow && OCCR\*h≥CNTR
- When the following two conditions are met, it is also considered to meet the conditions set by OCMR\*I.OPPKL:
  - CCSR.MODE=1 && Count overflow && OCCR\*I=0xFFFF
  - OCER\*.MCECL=1 && Count overflow && OCCR\*I≥CNTR

## 23 Emergency Brake Module (EMB)

### 23.1 Introduction

The emergency brake module is a function module that generates control events output to the timer when certain conditions are met to stop the timer or change the PWM signal output to the external motor. The following factors are used to generate control events:

- External port input level change
- Level of PWM output port occurs in phase (same high or same low)
- Voltage comparator comparison results
- System error occurred
- Write register software control

### 23.2 Functional Description

#### 23.2.1 EMB Channel Function Block Diagram

EMB is used to output a control event signal to the timer module with PWM function (Timer4, Timer6) when certain conditions are met, notifying the timer module to turn off the current PWM output. The EMB module has 7 groups, among which Group0-Group3 are used to control Timer6 and are set and selected by the Timer6 register; Group4-Group6 are used to control Timer4 and correspond to the 3 units of Timer4 respectively.

Figure 23-1 EMB Channel Function Block Diagram

23.2.2 EMB Structure Block Diagram

Figure 23-2 EMB Structure Block Diagram

23.2.3 Control PWM Signal Output When External Port Input Level Changes

EMB has 4 external ports to control PWM signal output when the input level changes. Each group can independently set 1 or more of the 4 external ports to be enable, and the port allocation is shown in the following table.

Table 23-1 EMB Port Allocation

| Port    | PIN Name              |
|---------|-----------------------|
| EMB_IN1 | PA11, PB2, PC5, PD7   |
| EMB_IN2 | PA6, PB11, PB12, PE15 |
| EMB_IN3 | PA7, PC2, PD9         |
| EMB_IN4 | PB15, PD4, PH2, PI4   |

When using external port input level changes to control PWM signal output, first set the enable bit, that is, the EMB control register EMB\_CTL1.PORTINENy (y=1-4) to be enable, and at the same time, set the control signal to be generated when the port level is high (INVSEL=0) or low (INVSEL=1) through EMB\_CTL1.INVSELy (y=1-4). Enable the filter function and set the filter clock as needed through EMB\_CTL2.NFENy (y=1-4) and EMB\_CTL2.NFSELy (y=1-4).

After the filter samples the input signal according to the filter clock, it filters using a method of three consistent comparisons. That is, when the filter clock samples the same level on the port three times, this level is considered as an active level and sent to the block. Levels that are consistent less than three times are considered as external interference and filtered out, not sent to the block.

When an active level that meets the conditions is generated on the port, the port input status EMB\_STAT.PORTINSTy (y=1-4) of the EMB status register is set, and at the same time, the port input control flag bit EMB\_STAT.PORTINFy (y=1-4) is set. An interrupt will be generated when EMB\_INTEN.PORTINEN=1.

The EMB control event selects registers EMB\_RLSSEL.PORTINRSELy (y=1-4) through releasing EMB. EMB\_STAT.PORTINSTy (y=1-4) or EMB\_STAT.PORTINFy (y=1-4) outputs the selection to Timer6 and Timer4. After receiving the control event, Timer6 and Timer4 can set the output port to high level, low level or high impedance state according to the register settings.

When releasing the control, if EMB\_RLSSEL.PORTINRSELy (y=1-4) =1, when the port input level becomes inactive, EMB\_STAT.PORTINSTy (y=1-4) is automatically cleared to zero, and the control event is immediately released. If EMB\_RLSSEL.PORTINRSELy (y=1-4) =0, after the port input level becomes inactive, the EMB status reset register EMB\_STATCLR.PORTINFCLR needs to be written to clear EMB\_STAT.PORTINF to 0 and release the control event.

#### 23.2.4 Stop PWM Signal Output When PWM Output Port Level Occurs In-phase (same high or same low)

When using, first set the enable bit, that is, the EMB control register EMB\_CTL1.PWMSENy (Group=0-3, y=0-7 or Group=4-6, y=0-2) to be enable, and at the same time, select the active level to be monitored through the EMB control register EMB\_CTL2.PWMLVy (Group=0-3, y=0-7 or Group=4-6, y=0-2).

After the settings are completed, EMB monitors the complementary PWM output signals of Timer6 and Timer4. When the output signals are the same high or the same low, the PWM output status EMB\_STAT.PWMST of the EMB status register is set, and at the same time, the PWM output in-phase control flag bit EMB\_STAT.PWMSF is set. An interrupt will be generated when EMB\_INTEN.PWMEN=1.

The EMB control event selects register EMB\_RLSSEL.PWMRSEL through EMB release. The selection is outputted to Timer6 and Timer4 via EMB\_STAT.PWMST or EMB\_STAT.PWMSF. After receiving the control event, Timer6 and Timer4 can set the output port to high level, low level or high impedance state according to the register settings.

When releasing control, if EMB\_RLSSEL.PWMRSEL=1, when the PWM output same high or same low state is released, EMB\_STAT.PWMST is automatically cleared to zero, and the control event is immediately released. If EMB\_RLSSEL.PWMST=0, after the PWM output same high or same low state is released, the EMB status reset register EMB\_STATCLR.PWMSFCLR needs to be written to clear EMB\_STAT.PWMSF to 0 and release the control event.

Group0-3 can be used to monitor the complementary PWM output signals of Timer6, Group4 is used to monitor the complementary PWM output signals of Timer4\_1, Group5 is used to monitor the complementary PWM output signals of Timer4\_2, Group6 is used to monitor the complementary PWM output signals of Timer4\_3.

Table 23-2 EMB Group Mapping Table

| Port Name                     | Function                                    | Corresponding Group                  | EMB_CTL1 Control Bit | EMB_CTL2 Control Bit |
|-------------------------------|---------------------------------------------|--------------------------------------|----------------------|----------------------|
| TMR6_<t>_PWMA<br>(<t> is 1-8) | Complementary PWM output signal of Timer6   | Group0<br>Group1<br>Group2<br>Group3 | PWMSEN7-<br>PWMSEN0  | PWMLV7-PWMLV0        |

### 23.2.5 Stop PWM Signal Output According to Voltage Comparator Compare Result

Each group of EMB can send control event signals to Timer6 and Timer4 according to the 4 groups of comparison results of the voltage comparator. For the settings of the comparator output results, refer to the relevant descriptions in the "Voltage Comparator (CMP) " chapter.

When using, first set the enable bit, that is, the EMB control register EMB\_CTL1.CMPENy (y=1-4) to be enable. When the comparator comparison result flag is set, the comparator status EMB\_STAT.CMPST of the EMB status register is set, and at the same time, the EMB comparator control flag bit EMB\_STAT.CMPF is set. An interrupt is generated when the interrupt enable register EMB\_INTEN.CMPINT-EN=1.

The control event of EMB selects register EMB\_RLSSEL.CMPRSEL through the EMB release. The selection is output to Timer6 and Timer4 via EMB\_STAT.CMPST or EMB\_STAT.CMPF. After receiving the control event signal, Timer6 and Timer4 can set the output port to high level, low level or high impedance state according to the register settings.

When releasing control, if EMB\_RLSSEL.CMPRSEL=1, when the comparator result becomes inactive, EMB\_STAT.CMPST is automatically cleared to zero, and the control event is immediately released. If EMB\_RLSSEL.CMPRSEL=0, after the comparator result becomes inactive, the EMB status reset register EMB\_STATCLR.CMPFCLR needs to be written to clear EMB\_STAT.CMPF to 0 and release the control event.

### 23.2.6 Stop PWM Signal Output when System Error Occurs

Each Group of EMB can send notification signals to Timer6 and Timer4 when a system error occurs. System error signals come from PVD detection, Cortex-M4 lock signal, SRAM ECC check error, external oscillator stop, Flash ECC check error and FCM frequency measurement abnormality.

When using, first set the enable bit, that is, the EMB control register EMB\_CTL1.SYSEN to be enable, and set the EMB\_CTL1.PVDEN, LOCKUPEN, SRAMECCERREN, OSCSTPEN, FLASHECCERREN, FCMERREN bits to enable the system error sources to be detected. When the selected system error source flag is set, the system error status EMB\_STAT.SYSST of the EMB status register is set, and at the same time, the EMB system error control flag EMB\_STAT.SYSF is set. An interrupt will also be generated when EMB\_INTEN.SYSINTEN=1.

The EMB control events are routed to Timer6 and Timer4 through EMB\_RLSSEL.SYSRSEL, based on the status of EMB\_STAT.SYSST or EMB\_STAT.SYSF. After receiving the control event signal, Timer6 and Timer4 can set the output port to high level, low level or high impedance state according to the register settings.

When releasing control, if EMB\_RLSSEL.SYSRSEL=1, when the system error signal becomes inactive, EMB\_STAT.SYSST is automatically cleared to zero, and the control event is immediately released. If EMB\_RLSSEL.SYSRSEL=0, after the system error signal becomes inactive, the EMB status reset register EMB\_STATCLR.SYSFCLR needs to be written to clear EMB\_STAT.SYSF to 0 and release the control event.

### 23.2.7 Write Register Software Control PWM Signal Output

The EMB software output enable control register (EMB\_SOE) allows users to send control signals to Timer6 and Timer4 directly through software setting and resetting. When the software controls the PWM output, no interrupt request is generated.

## 23.3 Register Description

### 23.3.1 Register List

- EMB Group0 Base Address: 0x40017C00
- EMB Group1 Base Address: 0x40017C20
- EMB Group2 Base Address: 0x40017C40
- EMB Group3 Base Address: 0x40017C60
- EMB Group4 Base Address: 0x40017C80
- EMB Group5 Base Address: 0x40017CA0
- EMB Group6 Base Address: 0x40017CC0

#### Note

EMB contains 7 Groups, namely Group0-6.

Table 23-3 Emergency Brake Module (EMB) Register Offset

| Offset | Register                    | Description                                            | Width |

### 23.3.3 EMB Control Register 1 (EMB\_CTL1) (Group4-6)

This register is a one-time write register, that is, it can only be written once after reset.

| Offset | Bit Position |          |          |              |          |               |         |         |         |         |          |           |           |           |           |          |          |    |    |    |    |    |   |         |         |         |       |        |        |        |        |    |    |    |

### 23.3.4 EMB Control Register 2 (EMB\_CTL2) (Group0-3)

This register is a one-time write register, that is, it can only be written once after reset.

### 23.3.5 EMB Control Register 2 (EMB\_CTL2) (Group4-6)

This register is a one-time write register, that is, it can only be written once after reset.

## 24 General Timer (TimerA)

### 24.1 Introduction

The General Timer A (TimerA) is a timer with a 16-bit counting width and 4-channel PWM output. The timer supports two waveform modes, triangle wave and sawtooth wave, and can generate various PWM waveforms (single-side aligned PWM, double-side symmetrical PWM); supports synchronous start of counter; the compare reference value register supports buffer function; supports cascading between units to achieve 32-bit counting; supports 2-phase quadrature encoding count and 3-phase quadrature encoding count. This product series is equipped with 12 TimerA units, supporting up to 48 PWM outputs.

### 24.2 Features

The basic functions and features of TimerA are shown in the table below:

Table 24-1 Basic Functions and Features of TimerA

|                |                                 |
|----------------|---------------------------------|
| Waveform mode  | Sawtooth wave, triangular wave  |
| Basic function | Up/Down-counting direction      |
|                | Synchronous startup counter     |
|                | Reference value buffer function |
|                | 32-bit cascading count          |
|                | Quadrature encoding count       |
|                | 4 PWM output                    |
|                | Compare match event output      |
| Interrupt type | Compare match interrupt         |
|                | Period match interrupt          |

## 24.3 Functional Description

### 24.3.1 TimerA Block Diagram

The basic block diagram of TimerA is shown in the figure. In the figure, "<t>" is the unit number, that is, "<t>" is 1-12. In the rest of this section, "<t>" refers to the unit number and will not be repeated here.

This series of products carries 12 units of TimerA, among which the bus clock and count clock of units 1 to 4 are both PCLK0 (in this case, the PCLK shown in the block diagram refers to PCLK0); the bus clock and count clock of units 5 to 12 are PCLK1 (in this case, the PCLK shown in the block diagram refers to PCLK1). The counting frequency division clock source of each unit and the sampling reference clock source of the port digital filter are the same as its bus clock and counting clock.

Figure 24-1 TimerA Basic Block Diagram

The following table lists the input and output ports of TimerA.

Table 24-2 TimerA Port List

| Port Name     | Direction    | Function                                                   |
|---------------|--------------|------------------------------------------------------------|
| TMRA_<t>_PWMm | Input/Output | Capture input event port or PWM output port (m=1-4)        |
| TMRA_<t>_CLKA | Input        | Quadrature encoder counting event input port               |
| TMRA_<t>_CLKB |              |                                                            |
| TMRA_<t>_TRIG | Input        | Hardware-triggered start, stop, and clear event input port |

### 24.3.2 Symmetric Units

TimerA unit 1 and unit 2 are symmetric units, as are unit 3 and unit 4, and so on. Symmetric units can be linked to achieve cascaded counting, synchronized start, and other functions, as described in the following sections.

### 24.3.3 Basic Actions

#### 24.3.3.1 Waveform Mode

TimerA has two basic counting wave modes: sawtooth wave mode and triangle wave mode. The basic waveforms of the two waveform modes are as follows:

Figure 24-2 Sawtooth Waveform (Counting Up)

Figure 24-3 Triangle Waveform

#### 24.3.3.2 Compare Output

Each TimerA unit contains 4 channels compare output (TMRA\_<t>\_PWMm), which can output a specified level when the count value matches the compare reference value. The TMRA\_CMPARm registers correspond to the count compare reference value for the TMRA\_<t>\_PWMm output ports. When the timer count value equals TMRA\_CMPARm, the TMRA\_<t>\_PWMm port outputs the specified level (m=1-4).

The output level of the TMRA\_<t>\_PWMm port at various timing events -- such as the start of counting, stop of counting, count compare match, and count period match -- can be configured using the STAC, STPC, CMPC, PERC, and FORC bits in PCONRm register (m=1-4). The diagram below illustrates an example of compare output action for Unit 1.

Figure 24-4 Compare Output Action

24.3.3.3 Capture Input

Each PWM output channel of every TimerA unit is equipped with a capture input function that stores the captured count value. When the CCONR.CAPMD bit in the Capture Control Register (CCONRm) is set to 1, the capture input function becomes active. At this point, when the corresponding capture input condition is selected and this condition is valid, the current count value is stored in the corresponding register (CMPARm) (m=1-4).

The capture input condition can select the internal capture action trigger event (selected by the TMRA\_TRGSELx register, for the specific register content, see the "TimerA Hardware Trigger Event Selection Register (TMRA\_TRGSELx) (x=0-3) " in the "Automatic Operation System (AOS) " chapter), TMRA\_<t>\_PWMm port input, etc. The specific condition selection can be set through the CCONRm.HICP bit (m=1-4).

The internal trigger event selection register is shared by all 12 units of TimerA, and the specific allocation is shown in the following table.

Table 24-3 TRGSEL Selection Relationship Table for Internal Trigger Events

| TimerA Unit | Event Classification                                                                 | Corresponding Selection Register |
|-------------|--------------------------------------------------------------------------------------|----------------------------------|
| TimerA_1    | Counter Trigger Events: TRGSEL selection events specified by HCONR, HCUPR, and HCDOR | TMRA_TRGSEL0                     |
| TimerA_2    |                                                                                      | TMRA_TRGSEL1                     |
| TimerA_3    |                                                                                      | TMRA_TRGSEL2                     |
| TimerA_4    |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_5    |                                                                                      | TMRA_TRGSEL0                     |
| TimerA_6    |                                                                                      | TMRA_TRGSEL1                     |
| TimerA_7    |                                                                                      | TMRA_TRGSEL2                     |
| TimerA_8    |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_9    |                                                                                      | TMRA_TRGSEL0                     |
| TimerA_10   |                                                                                      | TMRA_TRGSEL1                     |
| TimerA_11   |                                                                                      | TMRA_TRGSEL2                     |
| TimerA_12   |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_1    | Capture Action Trigger Events: TRGSEL selection events specified by CCONR            | TMRA_TRGSEL1                     |
| TimerA_2    |                                                                                      | TMRA_TRGSEL0                     |
| TimerA_3    |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_4    |                                                                                      | TMRA_TRGSEL2                     |
| TimerA_5    |                                                                                      | TMRA_TRGSEL1                     |
| TimerA_6    |                                                                                      | TMRA_TRGSEL0                     |
| TimerA_7    |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_8    |                                                                                      | TMRA_TRGSEL2                     |
| TimerA_9    |                                                                                      | TMRA_TRGSEL1                     |
| TimerA_10   |                                                                                      | TMRA_TRGSEL0                     |
| TimerA_11   |                                                                                      | TMRA_TRGSEL3                     |
| TimerA_12   |                                                                                      | TMRA_TRGSEL2                     |

The following figure shows an example of the capture input action.

Figure 24-5 Capture Input Action

### 24.3.4 Clock Source Selection

The TimerA count clock can be selected from the following sources:

1. 1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 division of PCLK (configured by BCSTR.L.CKDIV)
2. TMRA\_<t>\_TRIG port event input (configured by HCUPR.HCUPn or HCDOR.HCDO n) (n=8-9)
3. Internal counter trigger event input (configured by HCUPR.HCUP10 or HCDOR.HCDO10)
4. Count overflow or underflow event input for symmetric units (configured by HCUPR.HCUPn or HCDOR.HCDO n) (n=11-12)
5. TMRA\_<t>\_CLKA and TMRA\_<t>\_CLKB port quadrature encoder input (configured by HCUPR.HCUPn or HCDOR.HCDO n) (n=0-7)

When the clock source selection is set to 1, the timer operates in software counting mode. When set to others, the timer operates in hardware counting mode. In hardware counting mode, ensure that BCSTR.L.CKDIV is 0. Each count clock source is independent and can be enabled or disabled individually. When the hardware clocks are selected, the software clock is automatically disabled.

### 24.3.5 Count Direction

The counting direction of TimerA can be changed via software. The method of changing the counting direction may vary slightly depending on the selected waveform mode.

#### 24.3.5.1 Sawtooth Wave Count Direction

In sawtooth wave counting mode, the counting direction can be set either during the timer counting or when the counting is stopped. Once set, the direction changes immediately.

#### 24.3.5.2 Triangle Wave Count Direction

In the triangle wave counting mode, the counting direction is set when counting stops. The direction setting is disabled when counting is in progress.

### 24.3.6 Digital Filtering

Each unit's TMRA\_<t>\_CLKA, TMRA\_<t>\_CLKB, TMRA\_<t>\_TRIG, TMRA\_<t>PWMm (when capturing input function) port inputs have digital filtering functions. The filter function of each port can be enabled and the filter clock can be selected by setting the corresponding bits of the FCONR register and the CCONRm register (m=1-4).

When the port level sampled by the filter sampling reference clock remains consistent for 3 consecutive times, that level is transmitted as a active level and transmitted to the internal block. Levels with fewer than 3 consistent samples are filtered as external noise and not transmitted to the internal block. The figure below shows an example of TMRA\_1\_CLKA port filtering action.

Figure 24-6 Filtering Function of Clock Input Port

### 24.3.7 Synchronous Starting

The symmetric units of TimerA can realize software synchronous start or hardware synchronous start, and the odd unit synchronously starts the even unit.

When the BCSTRL.SYNST bit of the even unit in the symmetric unit is set to 1, the synchronous start function of the even unit and the odd unit is enable. At this time, if the software sets the BCSTRL.START bit of the odd unit to 1, the counter of the synchronized even unit starts software synchronous counting; if the hardware sets any bit in HCONR.HSTA1-0 of the even unit to 1, and the corresponding hardware event occurs, the counter of the synchronized even unit starts hardware synchronous counting. When the hardware synchronous count start function is selected, the corresponding bits of HCONR.HSTA1-0 of the synchronized even unit must also be set to active.

The following figure shows an example of software synchronization startup when BCSTRL.SYNST=1 of unit 2 is set.

Figure 24-7 Software Synchronization Action

In addition, the product is equipped with a Counter Synchronization Enable Register TMR\_SYNENRx ( $x=1-2$ ) to synchronously start all the timers (including Timer0, Timer2, Timer4, Timer6, TimerA) carried by the product. For usage details and register descriptions, refer to the "General Timer (Timer0)" chapter.

### 24.3.8 Buffer Function

A total of 4 compare reference registers (CMPARm) ( $m=1-4$ ) of TimerA can be used in pairs to implement the buffer function. That is, CMPAR2 is used as the buffer value of CMPAR1, CMPAR4 is used as the buffer value of CMPAR3. The buffer control register (BCONRm) ( $m=1-2$ ) controls the two groups of buffer functions respectively.

When the BCONRm.BEN ( $m=1-2$ ) bit is set, the buffer function becomes active. When the counter reaches a certain time point, a buffer transmission occurs (CMPAR2/4- $\rightarrow$  CMPAR1/3). The "Certain Time Point" includes the following situations:

1. In hardware counting mode, the counter reaches the overflow point (when HCUPR!=0), the underflow point (when HCDOR!=0), or a hardware clear action occurs for the counter.
2. In sawtooth counting mode (BCSTRL.MODE=0), the counter counts to the overflow point (BCSTRL.DIR=1) or underflow point (BCSTRL.DIR=0) or the hardware clears the counter.
3. In triangle wave counting mode (BCSTRL.MODE=1), count to peak point (BCSTRL.DIR=1 && BCONRm.BSE0=1) ( $m=1-2$ )
4. In triangle wave counting mode (BCSTRL.MODE=1), count to valley point (BCSTRL.DIR=0 && BCONRm.BSE1=1) ( $m=1-2$ )

When the BCONRm.BSEN bit is set, the buffer special function becomes active ( $m=1-2$ ). When the CNTNR of the symmetric unit is read, a buffer transmission occurs in the CMPAR of this unit (CMPAR2/4- $\rightarrow$  CMPAR1/3).

The figure below is a schematic diagram of buffer transmission in sawtooth mode.

Figure 24-8 Buffer Action in Sawtooth Mode

Figure 24-9 Buffer and Special Buffer Actions in Sawtooth Mode

### 24.3.9 Cascade Counting

As described in the "[Clock Source Selection](#)" section, when the clock source is set to 4, the counting clock of this unit is selected as the count overflow (count up or count down) event of the symmetric unit. This allows the two units to be cascade combined, creating a 32-bit counter. In cascaded counting, the CNTER register of the symmetric unit serves as the lower 16-bit counter, while the CNTER register of this unit serves as the upper 16-bit counter.

For example, in triangular up-counting mode (BCSTR.L.MODE=0, BCSTR.L.DIR=1), if unit 1 is configured to use PCLK as the counting clock and unit 2 is configured to use the overflow event of unit 1 as its counting clock source (TMRA\_HCUPR.HCUP11=1 in unit 2), then starting the counters of unit 2 and unit 1 (start unit 2 first, then unit 1) enables cascaded counting. In this configuration, unit 1's CNTER serves

as the lower 16-bit counter, and unit 2's CNTER serves as the upper 16-bit counter. The figure below is a schematic diagram of the cascade counting of units 1 and 2.

Figure 24-10 32-bit Cascade Counting Action

## 24.3.10 General PWM Output

### 24.3.10.1 Single-Side Aligned PWM Output

In sawtooth counting mode, each channel within a unit can be configured via various port control settings to achieve single-side aligned PWM output (aligned at the period match point). For example, by setting the output to toggle on compare match (PCONR.CMPC=0b11) and also to toggle on period match (PCONR.PERC=0b11), an edge-aligned PWM waveform can be generated within one counting period.

The figure below shows an example of single-side aligned PWM output waveform in sawtooth mode.

Figure 24-11 Example of Single-Side Aligned PWM Output

### 24.3.10.2 Double-Side Symmetric PWM Output

In triangle counting mode, each channel within a unit can be configured via various port control settings to achieve double-side symmetric PWM output, where the waveform is symmetrical around the counting peak point. Depending on the output relationship between channels, either independent PWM outputs or complementary PWM outputs can be realized.

The figure below shows an example of double-side symmetric PWM output waveforms for channels 1, 2, 3, and 4 in triangle mode. Among them, channels 1 and 2 can be used as a pair of complementary PWM outputs.

Figure 24-12 Example of Double-Side Symmetric PWM Output

### 24.3.11 Quadrature Encoding Count

By considering the TMRA\_<t>\_CLKA input as AIN input, the TMRA\_<t>\_CLKB input as BIN input, and the TMRA\_<t>\_TRIG input as ZIN input, TimerA can implement quadrature encoding counting of three inputs.

The individual actions of AIN and BIN of each unit can realize the position counting mode; the combined actions of AIN, BIN and ZIN of two units can realize the revolution counting mode. The unit used for position counting is called the position counting unit, and the unit used for revolution counting is called the revolution counting unit. In the revolution counting mode, every two units are combined with each other (unit 1 and 2 are combined; unit 3 and 4 are combined; unit 5 and 6 are combined; unit 7 and 8 are combined; unit 9 and 10 are combined; unit 11 and 12 are combined), and the position counting unit and the revolution counting unit in the combination can be specified arbitrarily.

The counting condition enable of AIN and BIN is realized by setting the quadrature relationship between TMRA\_<t>\_CLKA and TMRA\_<t>\_CLKB in the HCUPR register and the HCDOR register; the input action of ZIN is realized by setting the clear enable bit of the HCONR register of the position counting unit to clear the position timer, and by setting HCUPR register of the revolution unit to count the revolution timer.

#### 24.3.11.1 Position Counting Mode

The quadrature encoder position counting mode enables the implementation of basic counting, phase difference counting, and direction counting based on the input signals from AIN and BIN.

## Basic Counting

Basic counting uses the input clock from either the AIN or BIN port to count.

Figure 24-13 Position Mode-Basic Counting

## Phase Difference Counting

Phase difference counting operates based on the phase relationship between AIN and BIN. Depending on the configuration, the system can perform 1x counting, 2x counting, or 4x counting.

HCUPR.HCUP6=0b1 && HCDOR.HCDO4=0b1

Figure 24-14 Position Counting Mode-Phase Difference Counting (1x Counting)

HCUPR.HCUP6=HCUPR.HCUP5=0b1 && HCDOR.HCDO2=HCDOR.HCDO1=0b1

Figure 24-15 Position Counting Mode-Phase Difference Counting (2x Counting)

HCUPR.HCUP6=HCUPR.HCUP5=HCUPR.HCUP3=HCUPR.HCUP0=0b1  
HCDOR.HCDO7=HCDOR.HCDO4=HCDOR.HCDO2=HCDOR.HCDO1=0b1

Figure 24-16 Position Counting Mode-Phase Difference Counting (4x Counting)

### Direction Counting

Direction counting sets the AIN input as the direction control, and uses the BIN input as the counting clock.

Figure 24-17 Position Counting Mode-Direction Counting

### 24.3.11.2 Revolution Counting Mode

Quadrature encoding revolution mode refers to determining the revolution count by incorporating ZIN input events on the basis of AIN and BIN counting. In revolution counting mode, the Z phase count function, position overflow counting function, and mixed counting function can be implemented based on the counting method of the revolution timer.

#### Z-phase Counting

Z-phase counting refers to a counting operation in which the revolution counting unit performs counting based on the ZIN input, while the position counting unit is reset to zero.

Figure 24-18 Revolution Counting Mode-Z-phase Counting

### Position Overflow Counting

Position overflow counting refers to the situation where an overflow event is generated when the position counting unit's count overflows or underflows, thereby triggering the timer of the revolution counting unit to perform one count. (In this counting mode, the ZIN input does not trigger counting in the revolution counting unit or clear the position counting unit.)

The count up (count down) event Bits 12-11 of the HCUPR or HCDOR register of the revolution counting unit are enabled, and the overflow event of the position counting unit can trigger the revolution counting unit to count once.

Figure 24-19 Revolution Counting Mode-Position Overflow Counting

### Mixed Counting

Mixed counting refers to a combined counting method that integrates both Z-phase counting and position overflow counting. Its implementation method is also a combination of the above two counting methods.

Figure 24-20 Revolution Counting Mode-Mixed Counting

## 24.3.12 Interrupt and Events

TimerA contains 3 interrupt outputs and 3 event outputs, which are 1 comparison match interrupt and event, and 2 period match interrupts and events.

### 24.3.12.1 Compare Match Interrupt and Event

When a comparison match occurs between the CMPARM register and the count value, the STFLR.CMPFm bit will be set to 1. At this time, if the ICONR.ITENm bit is set to 1, the corresponding interrupt request (TMRA\_<t>\_CMP) will be triggered; if the ECONR.ETENm bit is set to 1, the corresponding event request (TMRA\_<t>\_CMP) will be triggered (m=1-4).

When the capture input active condition selected by the CCONRM register occurs, the capture input action occurs. At this time, if the ICONR.ITENm bit is set to 1, the corresponding interrupt request (TMRA\_<t>\_CMP) will be triggered; if the ECONR.ETENm bit is set to 1, the corresponding event request (TMRA\_<t>\_CMP) will be triggered (m=1-4).

The comparison match interrupts and comparison match events of the 4 reference value within each unit are not output independently. The comparison match interrupts are summarized into an interrupt output to the interrupt module through "OR logic" (see the "Interrupt Controller (INTC)" chapter), and the comparison match events are summarized into an event output through "OR logic" to select trigger other modules.

### 24.3.12.2 Period Match Interrupt and Event

The sawtooth wave mode counts up to the overflow point, the sawtooth wave mode counts down to the underflow point, and the triangle wave mode counts to the valley point or peak point. The BCSTRH.OVFF or BCSTRH.UDFF bit will be set to 1. At this time, if the BCSTRH.ITENOVF or BCSTRH.ITENUDF bit is

set to 1 to enable interrupts, the period match interrupt (TMRA\_<t>\_OVF and TMRA\_<t>\_UDF) can be triggered at the corresponding period point to be output to the interrupt module (INTC); the period match event has no corresponding enable bit control, and the period match event (TMRA\_<t>\_OVF and TMRA\_<t>\_UDF) output is triggered at the corresponding counting period point to select triggering other modules.

## 24.4 Register Description

### 24.4.1 Register List

- TimerA\_1 base address: 0x4003A000
- TimerA\_2 base address: 0x4003A400
- TimerA\_3 base address: 0x4003A800
- TimerA\_4 base address: 0x4003AC00
- TimerA\_5 base address: 0x40026000
- TimerA\_6 base address: 0x40026400
- TimerA\_7 base address: 0x40026800
- TimerA\_8 base address: 0x40026C00
- TimerA\_9 base address: 0x40027000
- TimerA\_10 base address: 0x40027400
- TimerA\_11 base address: 0x40027800
- TimerA\_12 base address: 0x40027C00

#### Note

TimerA is the name of the timer, and TimerA\_<t> (<t>: 1-12) is the timer unit.

Table 24-4 General Timer (TimerA) Register Offset

| Offset       | Register    | Description                                | Width |
|--------------|-------------|--------------------------------------------|-------|
| 0x0000       | TMRA_CNTER  | General Count Value Register               | 16    |

**Note**

- For TimerA Units 1 to 4, the PCLK source is PCLK0; for TimerA Units 5 to 12, the PCLK source is PCLK1.
- The TMRA\_<t>\_XOR signal is the signal obtained by performing an XOR operation on the quadrature inputs AIN and BIN of each unit.

## 25 General Timer (Timer2)

### 25.1 Introduction

General Timer 2 (Timer2) is a basic timer that can realize synchronous counting and asynchronous counting. The timer contains two channels (CH-A and CH-B). Each channel has an output port, which can realize basic square wave output. Each channel has two input ports, one is a clock input port, which can realize asynchronous port counting; the other one is a trigger input port, which can realize timer start, stop, clear, counting action and counting value capture input; support pulse width measurement and period measurement. This series of products is equipped with 4 units of Timer2.

### 25.2 Features

The basic functions and features of Timer2 are as follows:

Table 25-1 Basic Functions and Features of Timer2

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| Basic actions  | Hardware triggered counter start, stop, clear, count and capture inputs |
|                | Synchronous counting and asynchronous counting                          |
|                | Pulse width measurement                                                 |
|                | Period measurement                                                      |
|                | Square wave output                                                      |
|                | Event signal output                                                     |
| Interrupt type | Count comparison match interrupt                                        |
|                | Count overflow interrupt                                                |

### 25.3 Functional Description

#### 25.3.1 Basic Block Diagram

In the block diagram, the symbol "<t>" denotes the unit number, which ranges from 1-4. In the remainder of this section, "<t>" will consistently refer to the unit number and will not be further explained. The ANF on the TMR2\_<t>\_CLKA/B port input in the block diagram is an analog filter unit with a filter width of 40ns (typical conditions).

Figure 25-1 Timer2 Basic Block Diagram

The following table lists the input and output ports of Timer2.

Table 25-2 Timer2 Port List

| Port Name        | Direction | Function                                                                  |
|------------------|-----------|---------------------------------------------------------------------------|
| TMR2_<t>_CLKA/B  | Input     | Asynchronous clock input port                                             |
| TMR2_<t>_TRIGA/B | Input     | 1. Hardware start, stop, clear, count input port<br>2. Capture input port |
| TMR2_<t>_PWMA/B  | Output    | Square wave output port                                                   |

### 25.3.2 Clock Source Selection

Timer2 can be counted either synchronously or asynchronously.

The synchronous counting mode refers to the synchronous timing relationship between the timer count clock and the bus access clock (register read/write operation clock). Asynchronous counting means that the timer count clock and bus access clock (register read/write operation clock) are non-synchronous timing relationships. The status of a timer, etc., may be changing when the register is read by asynchronous counting. Therefore, in the asynchronous counting mode, the register read operation must be implemented in the count stopped state.

### Synchronous Count Timer

When operating in synchronous counting mode (BCONR.SYNSA<B>=0), the following clock sources can be selected (configured via BCONR.SYNCLKA<B>[1:0] or BCONR.SYNCLKA<B>T[1:0]) :

1. PCLK1 and its 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as synchronous count clock (BCONR.SYNCLKA<B>[1:0]=0b00, determined by BCONR.CKDIVA<B>[3:0]);
2. The input enable selection edge of TMR2\_<t>\_TRIGA and TMR2\_<t>\_TRIGB ports is sampled by the internal PCLK1 as the synchronous counting clock (BCONR.SYNCLKA<B>[1:0]=0b01 or 0b10);
3. An internal hardware trigger event input can serve as the synchronous count clock (BCONR.SYNCLKA<B>[1:0]=0b11);
4. Timer6 count overflow event (BCONR.SYNCLKA<B>T[0]=1);
5. Timer6 count underflow event (BCONR.SYNCLKA<B>T[1]=1).

#### Note

When the clock source is selected as 2, 3, 4, or 5, ensure that the PCLK1 division frequency is 1.

### Asynchronous Count Timer

In asynchronous counting mode (BCONR.SYNSA<B>=1), the clock source can be selected from the following options (BCONR.ASYNCLKA<B>[1:0] setting) :

1. LRC clock source input and its 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as asynchronous counting clocks (BCONR.ASYNCLKA<B>=0 & BCONR.CKDIVA<B>[3:0] settings);
2. XTAL32 clock source input and its 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as asynchronous counting clocks (BCONR.ASYNCLKA<B>=1 & BCONR.CKDIVA<B>[3:0] settings);
3. TMR2\_<t>\_CLKA, TMR2\_<t>\_CLKB clock input ports and their 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as asynchronous count clocks (BCONR.ASYNCLKA<B>=0b10 & BCONR.CKDIVA<B>[3:0] settings).

### 25.3.3 Compare Output

Timer2 has two output ports (TMR2\_<t>\_PWMA, TMR2\_<t>\_PWMB), which can realize basic square wave output.

The CMPAR and CMPBR registers correspond to the count compare references of TMR2\_<t>\_PWMA and TMR2\_<t>\_PWMB. When the count values CNTAR and CMPAR of the timer are equal, the TMR2\_<t>\_PWMA port outputs the specified level; when the count values CNTBR and CMPBR of the timer are equal, the TMR2\_<t>\_PWMB port outputs the specified level.

The count start level, stop level, and count comparison match level of the TMR2\_<t>\_PWMA/B port can be set by the PCONR.STACA<B>[1:0], PCONR.STPCA<B>[1:0], and PCONR.CMPCA<B>[1:0]. The figure below illustrates an example of the compare output behavior.

Figure 25-2 Compare Output Action

## 25.3.4 Hardware Triggering

### 25.3.4.1 Functional Overview

There are two types of hardware trigger actions for Timer2, one is the input event of TMR2\_<t>\_TRIGA/B port, and the other is the internal hardware trigger event. Both types of events can initiate actions such as start, stop, clear, and hardware capture input function. Various combinations of settings allow for the implementation of pulse width measurement, period measurement, and other functionalities.

The TMR2\_<t>\_TRIGA/B port input type selection (rising edge or falling edge) and function selection (start, stop, clear, capture input), and the function selection of the internal hardware trigger event (start, stop, clear, capture input) can be set through the corresponding bits of the hardware control register (HCONR).

Timer2 has an internal hardware trigger source. The event source can be selected by setting the corresponding number in the trigger selection register (TMR2\_TRGSEL). For specific event correspondence, please refer to the relevant description in the "Interrupt Controller (INTC)" chapter. When using the internal hardware trigger function, it is necessary to first enable the peripheral circuit trigger function at position 1 of the function clock control 0 register (PWC\_FCG0).

### 25.3.4.2 Start/Stop/Clear

The hardware start, stop, and clear conditions of each channel are determined by the relevant settings of HCONR register. The following figure is an example of the hardware start and clear action.

Figure 25-3 Hardware Start and Clear Action

### 25.3.4.3 Capture Input Action

When the TMR2\_<t>\_TRIGA/B port input or internal trigger Event is configured as the capture input condition, the capture input function can be implemented. When the capture input condition selected by the HCONR register is enabled, the current counter value is saved into the corresponding registers (CMPAR, CMPBR). The following figure shows an example of the capture input action.

Figure 25-4 Capture Input Action

### 25.3.4.4 Pulse Width Measurement

Set the hardware start condition for channel A to the rising edge of TMR2\_<t>\_TRIGA, and set the hardware clear condition, stop condition, and capture input condition to the falling edge of TMR2\_<t>\_TRIGA to achieve continuous pulse width measurement. Channel B can achieve the same function. The corresponding operation is illustrated in the figure below.

Figure 25-5 Pulse Width Measurement

### 25.3.4.5 Period Measurement

By setting the hardware start condition, hardware clear condition, and capture input condition of channel A to the same edge (rising or falling edge) of TMR2\_<t>\_TRIGA, continuous period width measurement can be achieved. Channel B can achieve the same function. The corresponding operation is illustrated in the figure below.

Figure 25-6 Period Measurement

### 25.3.5 Digital Filtering

The TRIG input port of Timer2 (TMR2\_<t>\_TRIGA/B) has a digital filter function. The filtering function of the corresponding port can be enabled by PCONR.NOFIENA<B> register. The reference clock for filtering is also set by the port control register (PCONR.NOFICKA<B>[1:0]).

When the port level sampled by the filter sampling reference clock remains consistent for 3 consecutive times, that level is transmitted as a active signal to the internal block. Levels with fewer than 3 consistent samples are filtered as external noise and not transmitted to the internal block. An example of this filtering behavior is shown in the figure below.

Figure 25-7 Digital Filtering of TRIG Input Port

### 25.3.6 Software Synchronization Start

The product is equipped with a count synchronization enable register (TMR\_SYNENR, TMR\_SYNENR2) to synchronously start the timer (including Timer0, Timer2, Timer4, Timer6, TimerA) carried out by the product. For usage and register description, please refer to the description in the "General Timer (Timer0)" chapter. Please do not use this function when this timer is counting asynchronously.

### 25.3.7 Interrupt and Events

#### 25.3.7.1 Interrupt Output

One Timer2 contains 4 interrupts, namely, the count compare match interrupt or capture input interrupt of channel A and channel B, and the count overflow interrupt of channel A and channel B.

There are two reference registers (CMPAR, CMPBR), which can be compared with the count value registers (CNTAR, CNTBR) to generate comparison match active signals. When the count compare matches, the STFLR.CMFA<B> will be set to 1. At this time, if the ICONR.CMENA<B> is set to enable interrupt, the corresponding interrupt request (TMR2\_<t>\_CMPm, m=A, B) will also be triggered.

When the capture input active condition selected by the hardware control register (HCONR) occurs, the corresponding capture input action can be generated. At this time, if the ICONR.CMENA<B> is set to enable interrupt, the corresponding interrupt request (TMR2\_<t>\_CMPm, m=A, B) is triggered.

When the count value register (CNTAR, CNTBR) counts to 0xFFFF, a count overflow event occurs. At this time, the STFLR.OVFA<B> will be set to 1. If the ICONR.OVENA<B> is set to enable interrupt, the corresponding interrupt request (TMR2\_<t>\_OVFm, m=A, B) will also be triggered.

When the asynchronous counting mode is selected (except BCONR.ASYNCLKA[1:0]=0b10), the compare match interrupt generated by the reference register (CMPAR) of unit 1 can be used to wake up the system in low power mode. Please refer to the relevant description in the "Interrupt Controller (INTC)" chapter.

#### 25.3.7.2 Event Output

One Timer2 contains 4 events, namely, the count compare match event or capture input interrupt of channel A and channel B, and the count overflow interrupt of channel A and channel B.

When a count compare match, capture input action or count overflow occurs during the counting process, a corresponding event request (TMR2\_<t>\_CMPm or TMR2\_<t>\_OVFm, m=A, B) output signal will be generated, which can be used to select and trigger other modules.

## 25.4 Register Description

### 25.4.1 Register List

- Timer2\_1 base address: 0x40024800
- Timer2\_2 base address: 0x40024C00
- Timer2\_3 base address: 0x40025000
- Timer2\_4 base address: 0x40025400

#### Note

Timer2 is the name of the timer, and Timer2\_<t> (<t>:1-4) is the timer unit.

Table 25-3 General Timer (Timer2) Register Offset

| Offset | Register   | Description                | Width |
|--------|------------|----------------------------|-------|
| 0x0000 | TMR2_CNTAR | Count Value Register       | 32    |

## 25.5 Precautions

1. During asynchronous counting operation, you must first configure the asynchronous clock source by setting the BCONR.ASYNCCLKA<B> bit, then select the asynchronous counting mode by setting the BCONR.SYNSA<B> bit, and finally start Timer2.
2. Under asynchronous counting mode, when the count value (CNTA<B>R), reference value (CMPA<B>R), start bit (BCONR.CSTA<B>), and status bit (STFLR.CMFA<B>, STFLR.OVFA<B>, STFLR.ICPA<B>) are modified, Timer2 will write the modified value into the corresponding register after 3 asynchronous counting clocks after receiving the write action.
3. Under asynchronous counting mode (BCONR.SYNSA<B>=0b1), when performing consecutive write actions to any of the following registers: CNTA<B>R, CMPA<B>R, BCONR.CSTA<B>, or the status bits (STFLR.CMFA<B>, STFLR.OVFA<B>, STFLR.ICPA<B>), you must wait until the status flag STFLR.SY-DA<B> becomes 1 before issuing the next write to any of these registers.
4. When asynchronous counting is selected, ensure that BCONR.SYNCLKA<B> is set to 0.
5. When using Timer2 events to trigger actions in other peripherals, the reference value register setting for the corresponding channel of Timer2 must be greater than 5.

## 26 General Timer (Timer0)

### 26.1 Introduction

General Timer 0 (Timer0) is a basic timer that can realize synchronous counting and asynchronous counting. The timer contains two channels (CH-A and CH-B) that can generate compare match events and count overflow events during counting. This event can trigger an interrupt and can be used to trigger other module actions. This series of products is equipped with 5 units of Timer0.

### 26.2 Functional Description

#### 26.2.1 Timer0 Block Diagram

Figure 26-1 Timer0 Basic Block Diagram

#### 26.2.2 Clock Source Selection

Timer0 can be counted either synchronously or asynchronously.

The synchronous counting mode refers to the synchronous timing relationship between the timer count clock and the bus access clock (register read/write operation clock). Asynchronous counting means that the timer count clock and bus access clock (register read/write operation clock) are non-synchronous timing relationships. The status of a timer, etc., may be changing when the register is read by asyncho-

nous counting. Therefore, in the asynchronous counting mode, the register read operation must be implemented in the count stopped state.

### Synchronous Count Clock Source

In synchronous counting mode ( $\text{BCONR.SYNSA} \langle B \rangle = 0$ ), the clock source can have the following options ( $\text{BCONR.SYNCLKA} \langle B \rangle$  setting) :

1. PCLK1 and PCLK1 divided by 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 are used as synchronous count clocks ( $\text{BCONR.SYNCLKA} \langle B \rangle = 0$  &  $\text{BCONR.CKDIVA} \langle B \rangle$  settings);
2. An internal hardware trigger event input can serve as the synchronous count clock ( $\text{BCONR.SYNCLKA} \langle B \rangle = 1$ );

### Asynchronous Count Clock Source

In asynchronous counting mode ( $\text{BCONR.SYNSA} \langle B \rangle = 1$ ), the clock source can be selected from the following options ( $\text{BCONR.ASYNCLKA} \langle B \rangle$  setting selection) :

1. LRC clock source input and its 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as asynchronous counting clocks ( $\text{BCONR.ASYNCLKA} \langle B \rangle = 0$  &  $\text{BCONR.CKDIVA} \langle B \rangle$  settings);
2. XTAL32 clock source input and its 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 divisions are used as asynchronous counting clocks ( $\text{BCONR.ASYNCLKA} \langle B \rangle = 1$  &  $\text{BCONR.CKDIVA} \langle B \rangle$  settings).

## 26.2.3 Basic Counting

Each channel of Timer0 can set the reference count value, and generate a count compare match event when the count value is equal to the reference value.

Figure 26-2 Timer0 Counting Timing Diagram

## 26.2.4 Hardware Triggering

Timer0 has two channels that share a common internal hardware trigger source. The timer's status (start, stop, reset) and capture input actions can be controlled through the relevant settings in the Basic Control Register (BCONR).

The source of this hardware trigger is selected by writing the corresponding trigger number into the Hardware Trigger Selection Register (TMR0\_TRGSEL). For details on the register contents, refer to the "Automatic Operation System (AOS) " section, and for the specific event mappings, refer to the "Interrupt Controller (INTC) " section. When using the internal hardware trigger function, the AOS function control bit in Function Clock Control 0 Register (PWC\_FCG0) must be enabled first.

## 26.2.5 Software Synchronization Start

The product is equipped with two counter synchronization enable registers (TMR\_SYNNR1 and TMR\_SYNNR2) used to synchronously start the timers integrated in the product, as shown in the table below (\* represents any TMR unit of a given type; TMR\* refers to any type of TMR). By setting multiple start bits in TMR\_SYNNR1 and TMR\_SYNNR2 to 1, multiple timers can begin counting simultaneously.

For specific bit assignments, please refer to the Counter Synchronization Enable Register (TMR\_SYNENR1 and TMR\_SYNENR2). Configure the TMR\_SYNENR1 register before configuring the TMR\_SYNENR2 register.

#### Notice

- When using the synchronous start function, ensure that all timers to be started synchronously operate with the same PCLK clock frequency and that the corresponding timer clocks (PWC\_FCG2) are enabled.
- When using the synchronous start function, please ensure that the timers that need to be started synchronously are in synchronous counting mode.
- The TMR\_SYNENR1 register must be written synchronously when the TMR\_SYNENR2 register is written, that is, setting the TMR\_SYNENR1 register alone has no effect.

**Table 26-1 Counter and PWM Synchronization Start Status**

| Synchronous start      | TMR unit             | Counter synchronization | PWM synchronization |

## 26.2.6 Interrupt and Event

### 26.2.6.1 Interrupt

One Timer0 contains 4 interrupt outputs, namely, the count compare match interrupt or capture input interrupt of channel A and channel B, and the count overflow interrupt of channel A and channel B.

There are 2 reference value registers (CMPAR, CMPBR), which can be compared with the count value registers (CNTAR, CNTBR) respectively to generate comparison matching active signals. When the count compare matches, the STFLR.CMFA<B> bit in the Status Flag Register (STFLR) will be set to 1. At this time, if the BCONR.CMENA<B> bit of the Basic Control Register (BCONR) is set to enable interrupt, the corresponding interrupt request (TMR0\_<t>\_CMPn, <t>=1-5; n=A, B) will also be triggered.

When the internal hardware trigger input is used as the capture input condition, the corresponding capture input action can be generated. At this time, if the BCONR.CMENA<B> bit of the Basic Control Register (BCONR) is set to enable interrupt, the corresponding interrupt request (TMR0\_<t>\_CMPn, <t>=1-5; n=A, B) is triggered.

When the count value register (CNTAR, CNTBR) counts to 0xFFFF, a count overflow event occurs. At this time, the STFLR.OVFA<B> bit in the Status Flag Register (STFLR) will be set to 1. If the BCONR.OVENA<B> bit of the Basic Control Register (BCONR) is set to enable interrupt, the corresponding interrupt request (TMR0\_<t>\_OVFn, <t>=1-5; n=A, B) will also be triggered.

When the asynchronous counting mode is selected, the compare match interrupt generated by the reference value register (CMPAR) of unit 1 can be used to wake up the system in Stop mode. Please refer to the relevant description in the "Interrupt Controller (INTC) " section.

#### 26.2.6.2 Event

One Timer0 has four event outputs, namely, the count compare match events or capture input events of channel A and channel B, and the count overflow events of channel A and channel B.

When a count compare match, capture input action or count overflow occurs during the counting process, a corresponding event request (TMR0\_<t>\_CMPn or TMR0\_<t>\_OVFn, <t>=1-5, n=A, B) output signal will be generated, which can be used to select and trigger other modules.

## 26.3 Register Description

### 26.3.1 Register List

- Timer0\_1 base address: 0x40024000
- Timer0\_2 base address: 0x40024400
- Timer0\_3 base address: 0x40029000
- Timer0\_4 base address: 0x40029400
- Timer0\_5 base address: 0x40029800

#### Note

Timer0 is the name of the timer, and Timer0\_<t> (<t>: 1-5) is the timer unit.

Table 26-2 General Timer (Timer0) Register Offset

| Offset | Register                   | Description                | Width |
|--------|----------------------------|----------------------------|-------|
| 0x0000 | <a href="#">TMR0_CNTAR</a> | Count Value Register A     | 32    |
| 0x0004 | <a href="#">TMR0_CNTBR</a> | Count Value Register B     | 32    |
| 0x0008 | <a href="#">TMR0_CMPAR</a> | Reference Value Register A | 32    |
| 0x000C | <a href="#">TMR0_CMPBR</a> | Reference Value Register B | 32    |
| 0x0010 | <a href="#">TMR0_BCONR</a> | Basic Control Register     | 32    |
| 0x0014 | <a href="#">TMR0_STFLR</a> | Status Flag Register       | 32    |

TMR\_SYNENR base address: 0x40055400

Table 26-3 TMR\_SYNENR Register Offset

| Offset | Register                    | Description                                | Width |
|--------|-----------------------------|--------------------------------------------|-------|

**Note**

The internal hardware trigger events (Bit31-Bit28 and Bit15-Bit12) and the XTAL32 clock source (Bit26 and Bit10) during asynchronous counting mentioned in this register are all provided by the USART module when the TIMEOUT function of the USART module is enabled. For details, please refer to the relevant description in the "Universal Synchronous Asynchronous Receiver/Transmitter (USART) " chapter.

| 0   | TMRA_1 | TimerA_1 Software Start Enable Bit | <ul style="list-style-type: none"> <li>0b0: TimerA unit 1 software start is disabled</li> <li>0b1: TimerA unit 1 software start is enabled, and the timer starts counting.</li> </ul> <div>  <b>Note</b><br/>Please use this function in synchronous counting mode. </div> | RW     |

 **Note**

1. Please do not use the count synchronization function in asynchronous counting mode for this timer.
2. TMR\_SYNNR2 is not controlled by the RMU\_FRST register.

## 26.4 Precautions

1. During asynchronous counting operation, you must first configure the asynchronous clock source by setting the BCONR.ASYNCCLKA<B> bit, then select the asynchronous counting mode by setting the BCONR.SYNSA<B> bit, and then start Timer0.
2. When asynchronous counting is selected, when the count value (CNTA<B>R), reference value (CMPAA<B>R), start bit (BCONR.CSTA<B>), and status bit (STFLR.CMFA<B>, STFLR.OVFA<B>, STFLR.ICPA<B>) are modified, Timer0 will write the modified value into the corresponding register after three asynchronous counting clocks after receiving the write action.
3. When selecting asynchronous counting, during consecutive write operations to the count value (CNTA<B>R), reference value (CMPA<B>R), start bit (BCONR.CSTA<B>), and status bits (STFLR.CMFA<B>, STFLR.OVFA<B>, STFLR.ICPA<B>), it is necessary to wait until the status bit (STFLR.SYDA<B>) is 1 before performing the next write operation to any of the aforementioned registers.
4. When asynchronous counting is selected, ensure that BCONR.SYNCLKA<B> is set to 0.

## 27 Real Time Clock (RTC)

### 27.1 Introduction

A real time clock (RTC) is a counter that stores time information in BCD format. Record the specific calendar time from 00 to 99. Support 12/24 hour time system, automatically calculate the number of days 28, 29 (leap year), 30 and 31 according to the month and year.

### 27.2 Features

**Table 27-1 RTC Main Features**

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

|                    | Backup register reset function                                                                                                                   |
| Interrupt          | Cycle interrupt                                                                                                                                  |
|                    | Alarm interrupt                                                                                                                                  |
|                    | Intrusion event interrupt                                                                                                                        |

## 27.3 Functional Description

### 27.3.1 RTC Block Diagram

Figure 27-1 RTC Basic Block Diagram

### 27.3.2 Power-on Setting

The RTC register value is uncertain after power-on reset. After power-on reset, you must first set the backup domain reset register PWC\_VBATRSTR, and then set the control register RTC\_CR0.RESET bit to reset all registers. Then set the control register, calendar initial value, alarm setting, and start RTC. After the RTC is started, other external reset requests cannot reset the RTC, and the RTC will always be in the working state. RTC operation can be stopped by setting the RTC\_CR1.START bit in the control register to 0. When setting the RTC, the clock source must be stable.

### 27.3.3 System Low Power Mode Switching

If the system switches to low-power mode immediately after RTC counting starts, please perform any of the following confirmations before switching modes.

- After setting RTC\_CR1.START=1, switch modes after more than 2 RTC count clocks.
- After setting RTC\_CR1.START=1, set RTC\_CR2.RWREQ=1 and query RTC\_CR2.RWEN=1. Set the calendar count register, then set RTC\_CR2.RWREQ=0, query RTC\_CR2.RWEN=0, and switch modes.

### 27.3.4 Clock Error Compensation

Due to deviations of the external low-speed crystal oscillator under varying temperature conditions, error compensation is required when high-accuracy counting results are needed. For the compensation method, refer to the "[Clock Error Compensation Registers \(RTC\\_ERRCRH and RTC\\_ERRCRL\)](#)".

### 27.3.5 Intrusion Detection

When intrusion detection RTC\_TPCRn.TPEN (n=0-1) is enabled, a active intrusion event detected on the external RTC pin can trigger the intrusion event detection function, timestamp function, and backup register reset function respectively.

**Intrusion Event Detection Function:** When an intrusion event occurs, the corresponding intrusion flag of the pin will be set. If the intrusion event continues, the overflow flag will be set. When intrusion event 0 and 1 occur simultaneously, the intrusion event 0 flag is set first, and after one RTC counting clock, the intrusion event 1 flag is set, and the overflow flag is also set. When the intrusion event interrupt enable RTC\_TPCRn.TPIE (n=0-1) is set, an intrusion detection interrupt will occur.

**Timestamp Function:** When RTC\_TPCRn.TSTPE (n=0-1) timestamp function is enabled, the timestamp register will record the second, minute, hour, day, and month calendar time when an intrusion event occurs.

**Backup Register Reset:** When RTC\_TPCRn.TPRSTE (n=0-1) backup register reset is enabled, the backup register will be reset after an intrusion event occurs. The backup registers consist of 32 32-bit registers, used to store 128 bytes of user backup data.

#### Notice

When intrusion detection is enabled, regardless of whether the timestamp function, intrusion event interrupt, or backup register reset function is enabled, the intrusion event flag RTC\_TPSRn.TPFn (n=0-1) will be set after an event occurs.

### 27.3.6 Timestamp Function

When the intrusion detection RTC\_TPCRn.TPEN (n=0-1) is enabled and the timestamp recording function RTC\_TPCRn.TSTPE (n=0-1) is enabled, the timestamp function will be triggered after the external pin of the RTC detects a active intrusion event. The timestamp register value will record the calendar time in seconds, minutes, hours, days and months. A set of timestamp registers corresponds to two intrusion event input pins respectively. When an intrusion event occurs on the pin for the first time, the intrusion flag is set and the timestamp is recorded. When an intrusion event occurs again, the overflow flag is set, but the timestamp register still maintains the first recorded value. After the intrusion flag register is cleared, the timestamp will be recorded again when an intrusion detection occurs.

### 27.3.7 Interrupt

RTC supports 3 interrupt types. Timing alarm interrupt, periodic interrupt and intrusion detection interrupt.

#### Alarm Interrupt

Alarm clock interrupt RTC\_ALM, when RTC\_CR2.ALMIE=1 and RTC\_CR2.ALME=1, if the current calendar time and the minute alarm clock register (RTC\_ALMMIN), the hour alarm clock register (RTC\_ALMHOUR), and the weekly alarm clock register (RTC\_ALM WEEK) equal, trigger the alarm interrupt. The alarm clock configures an independent flag register bit RTC\_CR2.ALMF, write 0 to the RTC\_CR2.ALMF bit to clear the alarm clock flag.

## Periodic Interrupt

Periodic interrupt RTC\_PRD, when RTC\_CR2.PRDIEN=1, after the selected period occurs, a periodic wake-up interrupt is triggered. The periodic interrupt is configured with an independent flag register RTC\_CR2.PRDF, and the periodic flag can be cleared by writing 0 to the RTC\_CR2.PRDF bit.

## Intrusion Detection Interrupt

When the intrusion detection is enabled RTC\_TPCRn.TPEN (n=0-1) and the intrusion event interrupt is enabled RTC\_TPCRn.TPIE (n=0-1), an intrusion event interrupt will occur after the external pin of the RTC detects a active intrusion event. Since the two groups of intrusion detection share one interrupt, they can be distinguished by the intrusion event detection interrupt flag bit RTC\_TPSR.TPFn (n=0-1).

# 27.4 Operation Example

## 27.4.1 RTC Count Start Setting

- Step1.** After power-on, first set the backup domain reset register PWC\_VBATRSTR, then set RTC\_CR0.RESET=0. After confirming that the RESET bit is 0, set RTC\_CR0.RESET=1 to reset all registers;
- Step2.** Set RTC\_CR1.START=0, stop counting;
- Step3.** Set the system clock register, turn on the external low-speed oscillator, then set RTC\_CR3 to select the RTC count clock source;
- Step4.** Set RTC\_CR1, set time, period, 1Hz clock output;
- Step5.** Set the calendar counting registers for seconds, minutes, hours, weeks, days, months, and years;
- Step6.** When clock error compensation is required, set the counting clock error compensation registers RTC\_ERRCRL, RTC\_ERRCRH;
- Step7.** Clear the flag register bits in registers RTC\_CR2, RTC\_TPSR, and enable interrupts;
- Step8.** Set RTC\_CR1.START=1, counting starts.

## 27.4.2 Read Count Register

- Step1.** After RTC\_CR1.START=1 is set, after more than 2 RTC count clocks, set RTC\_CR2.RWREQ=1 to make a calendar register read request;
- Step2.** Query until RTC\_CR2.RWEN=1;
- Step3.** Read all or part of the seconds, minutes, hours, weeks, days, months, and years counter register values;
- Step4.** Set RTC\_CR2.RWREQ=0;
- Step5.** Query until RTC\_CR2.RWEN=0.

## 27.4.3 Write Count Register

- Step1.** After setting RTC\_CR1.START=1, after more than 2 RTC counting clocks, set RTC\_CR2.RWREQ=1 to make a calendar register write request;
- Step2.** Query until RTC\_CR2.RWEN=1;
- Step3.** Write all or part of the seconds, minutes, hours, weeks, days, months, and years counter register values;
- Step4.** Set RTC\_CR2.RWREQ=0. Note that all write operations must be completed within 1 second;
- Step5.** Query until RTC\_CR2.RWEN=0.

### 27.4.4 Alarm Clock Setting

- Step1.** Set RTC\_CR2.ALME=0, the alarm clock is disabled;
- Step2.** Set RTC\_CR2.ALMIE=1, the alarm clock interruption permission;
- Step3.** Minute alarm clock RTC\_ALMMIN, hour alarm clock RTC\_ALMHOUR, week alarm clock RTC\_ALM-WEEK setting;
- Step4.** Set RTC\_CR2.ALME=1, alarm clock permission;
- Step5.** Wait for the alarm to interrupt;
- Step6.** When an alarm occurs, RTC\_CR2.ALMF=1, and the alarm interrupt processing begins.

### 27.4.5 1Hz Output

The RTC can output a 1Hz clock and provide three precision output methods:

1. Ordinary precision 1Hz output without clock compensation;
2. Distributed compensation 1Hz output with average compensation within every 32 seconds;
3. Uniform compensation 1Hz output per second.

When the clock error compensation function is enable RTC\_ERRCRH.COMPEN=1, the distributed compensation 1Hz output and the uniform compensation 1Hz output can be selected.

#### Ordinary Precision 1Hz Output

The 1Hz output of ordinary precision is set as follows:

- Step1.** Set RTC\_CR0.RESET=0, after confirming that the RESET bit is 0, set RTC\_CR0.RESET=1, reset the calendar count register;
- Step2.** Set RTC\_CR1.START=0, counting stops;
- Step3.** 1Hz output pin setting;
- Step4.** RTC\_CR1.ONEHZOE=1, clock output permission;
- Step5.** Set RTC\_CR1.START=1, start counting;
- Step6.** Wait for more than 2 count periods;
- Step7.** 1Hz output starts.

#### Distributed Compensation 1Hz Output

The distributed compensation 1Hz output setting is as follows:

- Step1.** Set RTC\_CR0.RESET=0, after confirming that the RESET bit is 0, set RTC\_CR0.RESET=1, reset the calendar count register;
- Step2.** Set RTC\_CR1.START=0, counting stops;
- Step3.** 1Hz output pin setting;
- Step4.** RTC\_CR1.ONEHZOE=1, clock output permission;
- Step5.** RTC\_CR1.ONEHZSEL=0, select to output distributed compensation 1Hz clock;
- Step6.** Clock error compensation register RTC\_ERRCRL.COMP[7:0] and RTC\_ERRCRH.COMP[8] compensation number setting;
- Step7.** Clock error compensation register RTC\_ERRCRH.COMPEN=1, error compensation is enabled;
- Step8.** Set RTC\_CR1.START=1, start counting;
- Step9.** Wait for more than 2 count periods;
- Step10.** 1Hz output starts.

#### Uniform Compensation 1Hz Output

Uniform compensation 1Hz output setting is as follows:

- Step1.** Set RTC\_CR0.RESET=0, after confirming that the RESET bit is 0, set RTC\_CR0.RESET=1, reset the calendar count register;
- Step2.** Set RTC\_CR1.START=0, counting stops;
- Step3.** RTC output pin setting;
- Step4.** RTC\_CR1.ONEHZOE=1, clock output permission;
- Step5.** RTC\_CR1.ONEHZSEL=1, select output uniform compensation 1Hz clock;
- Step6.** Clock error compensation register RTC\_ERRCRL.COMP[7:0] and RTC\_ERRCRH.COMP[8] compensation number setting;
- Step7.** Clock error compensation register RTC\_ERRCRH.COMPEN=1, accuracy compensation is enabled;
- Step8.** Set RTC\_CR1.START=1, start counting;
- Step9.** Wait for more than 2 count periods;
- Step10.** 1Hz output starts.

## 27.5 Register Description

### 27.5.1 Register List

Base address: 0x4004C000

Table 27-2 Real Time Clock (RTC) Register Offset

| Offset | Register    | Description                         | Width |
|--------|-------------|-------------------------------------|-------|
| 0x0000 | RTC_CR0     | Control Register 0                  | 8     |

### 27.5.6 Second Count Register (RTC\_SEC)

| Offset | Bit Position |      |   |   |      |   |   |   |
|--------|--------------|------|---|---|------|---|---|---|
| 0x0010 | 7            | 6    | 5 | 4 | 3    | 2 | 1 | 0 |
| Reset  | 0xXX         |      |   |   |      |   |   |   |
| Name   | Reserved     | SECD |   |   | SECU |   |   |   |
| Access |              | RW   |   |   | RW   |   |   |   |

| Bit | Name            | Function        | Description              | Access |
|-----|-----------------|-----------------|--------------------------|--------|
| 7   | <i>Reserved</i> | <i>Reserved</i> | -                        | -      |
| 6:4 | SECD            | Second Tens     | Second tens count value  | RW     |
| 3:0 | SECU            | Second Units    | Second units count value | RW     |

Indicates 0-59 seconds, using decimal counting. Please enter a decimal BCD code of 0 to 59. Values outside the range will be ignored.

### 27.5.7 Minute Count Register (RTC\_MIN)

| Offset | Bit Position |      |   |   |      |   |   |   |
|--------|--------------|------|---|---|------|---|---|---|
| 0x0014 | 7            | 6    | 5 | 4 | 3    | 2 | 1 | 0 |
| Reset  | 0xXX         |      |   |   |      |   |   |   |
| Name   | Reserved     | MIND |   |   | MINU |   |   |   |
| Access |              | RW   |   |   | RW   |   |   |   |

| Bit | Name            | Function        | Description              | Access |
|-----|-----------------|-----------------|--------------------------|--------|
| 7   | <i>Reserved</i> | <i>Reserved</i> | -                        | -      |
| 6:4 | MIND            | Minute Tens     | Minute tens count value  | RW     |
| 3:0 | MINU            | Minute Units    | Minute units count value | RW     |

Indicates 0-59 minutes, using decimal counting. Please enter a decimal BCD code of 0 to 59. Values outside the range will be ignored.

### 27.5.8 Hour Count Register (RTC\_HOUR)

| Offset | Bit Position |   |       |   |       |   |   |   |
|--------|--------------|---|-------|---|-------|---|---|---|
| 0x0018 | 7            | 6 | 5     | 4 | 3     | 2 | 1 | 0 |
| Reset  | 0xXX         |   |       |   |       |   |   |   |
| Name   | Reserved     |   | HOURD |   | HOURU |   |   |   |
| Access |              |   | RW    |   | RW    |   |   |   |

| Bit | Name     | Function   | Description            | Access |
|-----|----------|------------|------------------------|--------|
| 7:6 | Reserved | Reserved   | -                      | -      |
| 5:4 | HOURD    | Hour Tens  | Hour tens count value  | RW     |
| 3:0 | HOURU    | Hour Units | Hour units count value | RW     |

In 24-hour format, it means 0-23 hours.

In 12-hour format, it means 0-12 hours. Bit5=0 means AM, then 01-12 means morning; Bit5=1 means PM, then 01-12 means afternoon.

Please set the correct decimal 0-23 or 01-12, 01-12 BCD code according to the value of the control bit RTC\_CR1.AMPM. The value written out of range will be ignored.

For specific time values, please refer to the following table:

| 24-hour format (AMPM=1) |                | 12-hour format (AMPM=0) |                |
|-------------------------|----------------|-------------------------|----------------|
| Time                    | Register Value | Time                    | Register Value |
| 00 o'clock              | 0x00           | AM 12 o'clock           | 0x12           |
| 01 o'clock              | 0x01           | AM 01 o'clock           | 0x01           |
| 02 o'clock              | 0x02           | AM 02 o'clock           | 0x02           |
| 03 o'clock              | 0x03           | AM 03 o'clock           | 0x03           |
| 04 o'clock              | 0x04           | AM 04 o'clock           | 0x04           |
| 05 o'clock              | 0x05           | AM 05 o'clock           | 0x05           |
| 06 o'clock              | 0x06           | AM 06 o'clock           | 0x06           |
| 07 o'clock              | 0x07           | AM 07 o'clock           | 0x07           |
| 08 o'clock              | 0x08           | AM 08 o'clock           | 0x08           |
| 09 o'clock              | 0x09           | AM 09 o'clock           | 0x09           |
| 10 o'clock              | 0x10           | AM 10 o'clock           | 0x10           |
| 11 o'clock              | 0x11           | AM 11 o'clock           | 0x11           |
| 12 o'clock              | 0x12           | PM 12 o'clock           | 0x32           |
| 13 o'clock              | 0x13           | PM 01 o'clock           | 0x21           |

| 24-hour format (AMPM=1) |                | 12-hour format (AMPM=0) |                |

| 23 o'clock              | 0x23           | PM 11 o'clock           | 0x31           |

### 27.5.9 Day Count Register (RTC\_DAY)

| Offset | Bit Position |   |      |   |      |   |   |   |
|--------|--------------|---|------|---|------|---|---|---|
| 0x0020 | 7            | 6 | 5    | 4 | 3    | 2 | 1 | 0 |
| Reset  | 0xXX         |   |      |   |      |   |   |   |
| Name   | Reserved     |   | DAYD |   | DAYU |   |   |   |
| Access |              |   | RW   |   | RW   |   |   |   |

| Bit | Name     | Function  | Description           | Access |
|-----|----------|-----------|-----------------------|--------|
| 7:6 | Reserved | Reserved  | -                     | -      |
| 5:4 | DAYD     | Day Tens  | Day tens count value  | RW     |
| 3:0 | DAYU     | Day Units | Day units count value | RW     |

Represents 1 to 31 days, using decimal counting, automatically calculate leap years and months. Write BCD codes corresponding to decimal values 1-28, 1-29, 1-30, or 1-31. Values outside the range will be ignored.

Refer to the table below for the specific range of day values.

| Month                                                   | Day Count Value |
|---------------------------------------------------------|-----------------|
| February (normal year)                                  | 01-28           |
| February (leap year)                                    | 01-29           |
| April, June, September, November                        | 01-30           |
| January, March, May, July, August, October and December | 01-31           |

## 27.5.10 Week Count Register (RTC\_WEEK)

| Offset | Bit Position |   |   |   |   |      |   |   |
|--------|--------------|---|---|---|---|------|---|---|
| 0x001C | 7            | 6 | 5 | 4 | 3 | 2    | 1 | 0 |
| Reset  | 0xXX         |   |   |   |   |      |   |   |
| Name   | Reserved     |   |   |   |   | WEEK |   |   |
| Access |              |   |   |   |   | RW   |   |   |

| Bit | Name     | Function | Description      | Access |
|-----|----------|----------|------------------|--------|
| 7:3 | Reserved | Reserved | -                | -      |
| 2:0 | WEEK     | Week     | Week count value | RW     |

Decimal 0-6 means Sunday-Saturday. Please enter a decimal BCD code of 0 to 6. Values outside the range will be ignored.

For specific week count values, please refer to the following table:

| Week      | Week Count |
|-----------|------------|
| Sunday    | 0x00       |
| Monday    | 0x01       |
| Tuesday   | 0x02       |
| Wednesday | 0x03       |
| Thursday  | 0x04       |
| Friday    | 0x05       |
| Saturday  | 0x06       |

27.5.11 Month Count Register (RTC\_MON)

| Offset | Bit Position |   |   |     |   |   |   |   |
|--------|--------------|---|---|-----|---|---|---|---|
| 0x0024 | 7            | 6 | 5 | 4   | 3 | 2 | 1 | 0 |
| Reset  | 0xXX         |   |   |     |   |   |   |   |
| Name   | Reserved     |   |   | MON |   |   |   |   |
| Access |              |   |   | RW  |   |   |   |   |

| Bit | Name     | Function | Description       | Access |
|-----|----------|----------|-------------------|--------|
| 7:5 | Reserved | Reserved | -                 | -      |
| 4:0 | MON      | Month    | Month count value | RW     |

Indicates 1-12 months, using decimal counting. Write BCD-coded values corresponding to decimal 1-12. Values outside the range will be ignored.

### 27.5.12 Year Count Register (RTC\_YEAR)

| Offset | Bit Position |   |   |   |       |   |   |   |
|--------|--------------|---|---|---|-------|---|---|---|
| 0x0028 | 7            | 6 | 5 | 4 | 3     | 2 | 1 | 0 |
| Reset  | 0xXX         |   |   |   |       |   |   |   |
| Name   | YEAR         |   |   |   | YEARU |   |   |   |
| Access | RW           |   |   |   | RW    |   |   |   |

| Bit | Name  | Function   | Description            | Access |
|-----|-------|------------|------------------------|--------|
| 7:4 | YEARD | Year Tens  | Year tens count value  | RW     |
| 3:0 | YEARU | Year Units | Year units count value | RW     |

Indicates a year value from 0 to 99 in decimal counting, incremented based on month overflow. Automatically calculate leap years such as: 00, 04, 08,..., 92, 96, etc. Write BCD-coded values corresponding to decimal 0-99. Values outside the range will be ignored.

### 27.5.13 Minute Alarm Register (RTC\_ALMMIN)

| Offset | Bit Position |         |   |   |   |         |   |   |
|--------|--------------|---------|---|---|---|---------|---|---|
| 0x002C | 7            | 6       | 5 | 4 | 3 | 2       | 1 | 0 |
| Reset  | 0xXX         |         |   |   |   |         |   |   |
| Name   | Reserved     | ALMMIND |   |   |   | ALMMINU |   |   |
| Access |              | RW      |   |   |   | RW      |   |   |

| Bit | Name     | Function           | Description                    | Access |
|-----|----------|--------------------|--------------------------------|--------|
| 7   | Reserved | Reserved           | -                              | -      |
| 6:4 | ALMMIND  | Minute Alarm Tens  | Minute Alarm Tens count value  | RW     |
| 3:0 | ALMMINU  | Minute Alarm Units | Minute Alarm Units count value | RW     |

Indicates 0-59 points, using decimal counting. Please write the BCD code of decimal 0-59, and the alarm clock matching will not occur if you write the value out of range.

### 27.5.14 Hour Alarm Register (RTC\_ALMHOUR)

| Offset | Bit Position |   |          |   |          |   |   |   |
|--------|--------------|---|----------|---|----------|---|---|---|
| 0x0030 | 7            | 6 | 5        | 4 | 3        | 2 | 1 | 0 |
| Reset  | 0xXX         |   |          |   |          |   |   |   |
| Name   | Reserved     |   | ALMHOURD |   | ALMHOURU |   |   |   |
| Access |              |   | RW       |   | RW       |   |   |   |

| Bit | Name     | Function         | Description                  | Access |
|-----|----------|------------------|------------------------------|--------|
| 7:6 | Reserved | Reserved         | -                            | -      |
| 5:4 | ALMHOURD | Hour Alarm Tens  | Hour Alarm Tens count value  | RW     |
| 3:0 | ALMHOURU | Hour Alarm Units | Hour Alarm Units count value | RW     |

Depending on the value of the control bit RTC\_CR1.AMPM, set the correct decimal 0~23 or 01~ 12,21 ~32 BCD code. If an out-of-range value is written, the alarm match will not occur.

### 27.5.15 Week Alarm Register (RTC\_ALMWEEK)

| Offset | Bit Position |         |   |   |   |   |   |   |
|--------|--------------|---------|---|---|---|---|---|---|
| 0x0034 | 7            | 6       | 5 | 4 | 3 | 2 | 1 | 0 |
| Reset  | 0xXX         |         |   |   |   |   |   |   |
| Name   | Reserved     | ALMWEEK |   |   |   |   |   |   |
| Access |              | RW      |   |   |   |   |   |   |

| Bit | Name     | Function   | Description                                                                                                                                                                                                                                                                                | Access |
|-----|----------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 7   | Reserved | Reserved   | -                                                                                                                                                                                                                                                                                          | -      |
| 6:0 | ALMWEEK  | Week Alarm | Week Alarm Match Value<br>Bit0-Bit6 correspond to Sunday-Saturday respectively. When the corresponding position is 1, it means that the alarm is enable on that day of the week.<br>For example: Setting Bit0=1 and Bit5=1 means that the alarm settings on Sunday and Friday are enabled. | RW     |

Decimal 0-6 means Sunday-Saturday. Please enter a decimal BCD code of 0 to 6. Values outside the range will not trigger an alarm match.

## 27.5.16 Clock Error Compensation Register (RTC\_ERRCRH, RTC\_ERRCRL)

## RTC\_ERRCRH

| Offset | Bit Position |          |   |   |   |   |   |         |
|--------|--------------|----------|---|---|---|---|---|---------|
| 0x0038 | 7            | 6        | 5 | 4 | 3 | 2 | 1 | 0       |
| Reset  | 0xXX         |          |   |   |   |   |   |         |
| Name   | COMPEN       | Reserved |   |   |   |   |   | COMP[8] |
| Access | RW           |          |   |   |   |   |   | RW      |

| Bit | Name     | Function            | Description                                                                                                                             | Access |
|-----|----------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|--------|
| 7   | COMPEN   | Compensation enable | <ul style="list-style-type: none"> <li>0b0: Clock error compensation disabled</li> <li>0b1: Clock error compensation enabled</li> </ul> | RW     |

| Name   | COMP[7:0]    |   |   |   |   |   |   |   |
| Access | RW           |   |   |   |   |   |   |   |

| Bit | Name      | Function           | Description                                                                                                                                                                                                                                                                                                                                                   | Access |
|-----|-----------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 7:0 | COMP[7:0] | Compensation value | Through the setting of compensation values, an accuracy compensation of $\pm 0.96\text{ppm}$ per second can be achieved. The compensation value is 9 bits of 2's complement with a decimal point, and the last 5 bits are the decimal part. The compensation range is $-275.5\text{ppm}$ to $+212.9\text{ppm}$ . The minimum resolution is $0.96\text{ppm}$ . | RW     |

Please refer to the following table for specific compensation accuracy:

| Compensation Value Setting |           |   |   |   |   |   |   |   |   | Compensation Value |
|----------------------------|-----------|---|---|---|---|---|---|---|---|--------------------|
| COMP-EN                    | COMP[8:0] |   |   |   |   |   |   |   |   |                    |
| 1                          | 1         | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | -275.5ppm          |

| Compensation Value Setting |           |   |   |   |   |   |   |   |   | Compensation Value |
|----------------------------|-----------|---|---|---|---|---|---|---|---|--------------------|

| 0                          | X         | X | X | X | X | X | X | X | X | Uncompensated      |

### Compensation Calculation Instructions

When the 1Hz clock is directly output in the default state, the compensation target value is calculated by measuring the accuracy of the clock.

Assuming that the actual measured value is 0.9999888Hz, then:

Actual Vibration Frequency =  $32768 \times 0.9999888 \approx 32767.63$

Compensation Target Value =  $(\text{Actual Vibration Frequency} - \text{Target Frequency}) / \text{Target Frequency} \times 10^6$   
 $= (32767.63 - 32768) / 32768 \times 10^6$   
 $= -11.29\text{ppm}$

Based on the formula:

$$\text{COMP}[8:0] = \left( \frac{\text{Compensation Target Value [ppm]} \times 2^{15}}{10^6} \right)_{\text{Take 2's complement}} + 0b0001.00000$$

If the compensation target value is +20.3ppm, calculate the corresponding register value as follows:

$\text{COMP}[8:0] = (20.3 \times 2^{15} / 10^6)_{\text{takes 2's complement}} + 0b0001.00000$   
 $= (0.6651904)_{\text{takes 2's complement}} + 0b0001.00000$   
 $= 0b0000.10101 + 0b0001.00000$   
 $= 0b0001.10101$

If the compensation target value is -20.3ppm, calculate the corresponding register value as follows:

$\text{COMP}[8:0] = (-20.3 \times 2^{15} / 10^6)_{\text{takes 2's complement}} + 0b0001.00000$   
 $= (-0.6651904)_{\text{takes 2's complement}} + 0b0001.00000$   
 $= 0b1111.01011 + 0b0001.00000$   
 $= 0b0000.01011$

## 27.5.17 Intrusion Control Register0 (RTC\_TPCR0)

| Offset | Bit Position |        |       |         |       |   |       |   |

## 28 Watchdog Timer (WDT/SWDT)

### 28.1 Introduction

This product has two watchdog timers: one is a specialized watchdog timer (SWDT) with a dedicated internal RC (SWDTLRC: 10kHz) as the counting clock source, and the other is a universal watchdog timer (WDT) with a PCLK3 as the counting clock source. SWDT and WDT are 16-bit down-counters designed to detect software faults caused by applications deviating from normal operation due to external interference or unforeseen logical conditions.

Both watchdogs support the window function. The window interval can be preset before the count starts, and when the count value is within the window interval, the counter can be refreshed and the count restarted.

### 28.2 Features

Table 28-1 Basic Features of Watchdog Timer

|                            |                                                                                                                                                                                                                                                                                                                                                  |

### 28.3 Functional Description

#### 28.3.1 Start the Watchdog

Watchdog counter can be started in two ways: Hardware startup mode and software startup mode.

The hardware startup mode refers to the setting of the watchdog counter (ICG0 register) read from the main flash memory area during startup, and the counter automatically starts counting. The software startup mode refers to the process where, after setting the control register, the refresh register is written to complete the refresh action, and the counter starts counting.

### 28.3.2 Hardware Startup Mode

When the ICG0.WDTAUTS/SWDTAUTS is set to 0, it is the hardware startup mode. WDT/SWDT\_CR settings are ignored in hardware startup mode.

In hardware start mode, the WDT/SWDT-related settings (counting clock, window setting value, counting period, etc.) in the ICG0 register are loaded into the WDT/SWDT module during the reset period. After the reset, the counter automatically starts counting according to the settings. The figure below shows a hardware start mode example.

Figure 28-1 Hardware Startup Mode Example

### 28.3.3 Software Startup Mode

When the ICG0.WDTAUTS/SWDTAUTS is set to 1, WDT/SWDT is started via refresh register (software start mode). After reset, set the counting clock, window setting value, counting period, etc. in the WDT/SWDT\_CR register, and then perform the refresh action, and the counter starts to count. WDT/SWDT\_CR can be configured only once; subsequent writes are inactive. The figure below shows a software start mode example.

Figure 28-2 Software Startup Mode Example

### 28.3.4 Refresh Action

A refresh sequence (write 0x0123 followed by 0x3210 to WDT/SWDT\_RR) starts or restarts the counter (software start mode).

Writing 0x0123 and 0x3210 to WDT/SWDT\_RR register is unaffected by other register accesses or reads during the refresh sequence.

The figure below shows an operation example.

Figure 28-3 Examples of Various Refresh Action Sequences (action confirmation, refresh required signal falling edge, etc.)

Refresh operations require 4 clock periods to update the counting. Therefore, complete the writing of the refresh register 4 count values in advance of refreshing the lower window and the overflow position. Check the status register for the count value.

### 28.3.5 Flag Bit

Refresh error flag bit and underflow flag bit remain set if an interrupt is requested. Upon entering an interrupt, check the flag bit to identify the cause.

Clear the flag bit: Read "1" first, then write "0".

**Note**

Within a certain period of time when a refresh error or underflow error occurs, the clear operation of the flag bit has no effect. This period of time is: 1 counting period +2 SWDTLRC (SWDT module); 1 counting period +2 PCLK3 (WDT module).

When refreshing error flag bit and underflow flag bit, the counting of the hardware watchdog does not stop; while counting stops in software start mode. When writing "0" to the flag bit, the SWDT needs at most 3 SWDTLRC and 2 PCLK3 times before the register bit can be clear to 0. It takes at most five PCLK3 times for the register bit of WDT to be clear to 0. After clearing the flag bit, it is necessary to re-read the flag bit to confirm whether the clearing operation is successful.

Flag bit clearing procedures:

- Step1.** Read WDT/SWDT\_SR to check the flag bit.
- Step2.** Write "0" to the flag bit set to "1".
- Step3.** Read WDT/SWDT\_SR to confirm if the flag bit is cleared. Repeat Step 2 if the flag bit remain 1.

### 28.3.6 Interrupt/Reset

WDT/SWDT can trigger interrupt or reset requests upon counter underflow or refresh error. In hardware startup mode, generate an interrupt or a reset request depending on ICG0.WDTITS/SWDTITS bit. In software startup mode, set the WDT/SWDT\_CR.ITS bit to select interrupt or reset request.

WDT/SWDT generates interrupt/reset requests under 2 conditions. One is that counter counts produce underflow; One is to perform a refresh action outside the refresh allowed interval, resulting in a refresh error.

### 28.3.7 Count Underflow

As shown in the following figure, underflow occurs when the counter decrements to 0.

Figure 28-4 Counter Underflow Operation Example

### 28.3.8 Refresh Error

After setting the window range, the counter is refreshed and re-counting only when the refresh action is performed within the window range. A refresh error occurs when the refresh action is performed outside the window range. The figure below shows a refresh operation example.

Figure 28-5 Counter Refresh Operation Example

## 28.4 Register Description

### 28.4.1 Register List

WDT base address: 0x40049000

Table 28-2 Watchdog Timer (WDT) Register Offset

| Offset | Register | Description          | Width |
|--------|----------|----------------------|-------|
| 0x00   | WDT_CR   | WDT Control Register | 32    |
| 0x04   | WDT_SR   | WDT Status Register  | 32    |
| 0x08   | WDT_RR   | WDT Refresh Register | 32    |

SWDT base address: 0x40049400

| Access |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

| Bit   | Name     | Function      | Description                                                                                                                                          | Access |
|-------|----------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 31:16 | Reserved | Reserved      | -                                                                                                                                                    | -      |
| 15:0  | RF       | Refresh value | Write 0x0123 and 0x3210 to complete the refresh. After writing 0x0123, the register reads as 0x00000001; in all other cases, it reads as 0x00000000. | RW     |

## 28.5 Precautions

During SWDT operation, the frequency of the peripheral clock PCLK3 must equal to or greater than 4 timers of counting clock frequency. That is, PCLK3 frequency  $\geq$  counting clock frequency  $\times$  4.

## 29 Universal Synchronous Asynchronous Receiver/Transmitter (USART)

### 29.1 Introduction

This product is equipped with 10 units of Universal Synchronous Asynchronous Receiver/Transmitter (USART) modules, which can flexibly exchange full-duplex data with external devices; the USART equipped in this product supports universal asynchronous serial communication interface (UART), clock synchronous communication interface, smart card interface (ISO/IEC7816-3) and LIN communication interface. Support modem operation (CTS/RTS operation), multiprocessor operation, DE function. UART receive timeout function is supported by cooperating with the Timer0 module. USART1 supports the STOP mode wake-up function via the RX line.

### 29.2 Features

#### USART Features

- Support full-duplex asynchronous communication and full-duplex clock synchronous communication
- Support LIN bus
- Support smart card interface (ISO/IEC7816-3)
- Transmitter and receiver have independent enable bits
- Built-in double buffer
- LSB/MSB optional
- Support modem operation (CTS/RTS)
- Transmission flag: transmit data register empty, transmit data complete, receive data register full, receive error flag, UART receive timeout flag, LIN wake-up signal detection flag, LIN interval segment detection flag, LIN bus error flag
- Support RS485 Driver Enable function

#### UART Features

- Data length programmable: 8 bits/9 bits
- Parity function configurable: odd parity/even parity/no parity
- Stop bit configurable: 1 bit/2 bits

- Clock source optional: internal clock source (clock generated by internal baud rate generator) /external clock source (clock input from USARTn\_CK pin)
- Receive error: parity error, frame error, overflow error
- Support for inter-processor communications
- Built-in digital filter
- Supports receiving data TIMEOUT function
- Unit 1 supports Stop mode wake-up function
- Supports full-duplex/half-duplex communication mode

#### Clock Synchronization Mode Features

- Data length: 8 bits
- Receive error: overflow error
- Clock source: internal clock source (clock generated by internal baud rate generator) /external clock source (clock input by USARTn\_CK pin)
- Supports full-duplex communication mode

#### Smart Card Interface Features

- Data length: 8 bits
- When a parity error is detected, it can automatically send out an error signal
- Support data retransmission

#### LIN Features

- Data length: 8 bits
- Supports wake-up signal detection
- Supports 10/11-bit synchronization interval segment (BF: Break Field) detection
- Supports synchronization segment measurement, register records measurement value
- Supports 10/11/13/14-bit interval segment (BF) transmission
- Supports bus conflict detection
- Supports loop mode

## 29.3 Functional Description

### 29.3.1 System Block Diagram

#### Note

The value of n is 1-10.

## 29.3.2 UART Function

### 29.3.2.1 Clock

The UART can select either the clock generated by the internal baud rate generator (internal clock source) or the clock input from the USARTn\_CK pin (external clock source) as the communication clock source.

#### Internal Clock Source

When USARTn\_CR2.CLKC bit is set to 0b00 or 0b01, the clock source is selected as the internal clock source, i.e., the clock generated by the internal baud rate generator.

- When USARTn\_CR2.CLKC=0b00, the USARTn\_CK pin is not used as a clock pin and can function as a general-purpose IO.
- When USARTn\_CR2.CLKC=0b01, the USARTn\_CK pin outputs a clock with the same frequency as the communication baud rate.

When USARTn\_PR.ULBREN is 0, the clock source of the internal baud rate generator is selected by the USARTn\_PR.PSC bit setting as PCLK1, PCLK1/4, PCLK1/16, PCLK1/64. When USARTn\_PR.ULBREN is 1, the ultra-low baud rate function is enabled, and the clock source of the internal baud rate generator is selected by the USARTn\_PR.PSC bit setting as PCLK1/128, PCLK1/256, PCLK1/512, PCLK1/1024.

#### External Clock Source

When USARTn\_CR2.CLKC bit is set to 0b10 or 0b11, the clock source is selected as the external clock input from the USARTn\_CK pin. The input clock frequency is 16 times the Baud rate (when USARTn\_CR1.OVER8=0) or 8 times the Baud rate (when USARTn\_CR1.OVER8=1).

#### Maximum Baud Rate

When the internal clock source is selected, the baud rate generated by the internal baud rate generator is calculated using the following formula:

$$B = \frac{C}{8 \times (2 - \text{OVER8}) \times (\text{DIV\_Integer} + 1)}$$

Where:

- B: Baud rate, unit: Mbps
- C: When USARTn\_PR.ULBREN is 0, the clock set by USARTn\_PR.PSC bit (PCLK1, PCLK1/4, PCLK1/16, PCLK1/64), unit: MHz  
When USARTn\_PR.ULBREN is 1, the clock set by USARTn\_PR.PSC bit (PCLK1/128, PCLK1/256, PCLK1/512, PCLK1/1024), unit: MHz
- OVER8: USARTn\_CR1.OVER8 setting value
- DIV\_Integer: USARTn\_BRR.DIV\_Integer setting value

Maximum Baud Rate is PCLK1/8 (Mbps).

When using an External Clock Source, the maximum frequency requirement for the external input UART Clock is PCLK1/4 (MHz). Therefore, when the Clock Source is an external input clock:

- If USARTn\_CR1.OVER8=0, the Maximum Baud Rate is PCLK1/64 (Mbps).
- If USARTn\_CR1.OVER8=1, the Maximum Baud Rate is PCLK1/32 (Mbps).

Please note that in addition to the PCLK1-based calculation method described above for the maximum UART baud rate, you must also refer to the maximum communication baud rate specified in the "Electrical Specifications" chapter in the Datasheet.

### 29.3.2.2 Data Format

A frame of data in UART mode consists of start bit, data bit, check bit, and stop bit.

Figure 29-2 UART Data Format

- **Start Bit (ST)** : The start bit is always composed of one bit at Low level.
- **Data Bit (D)** : The data bit can be configured as 8-bit or 9-bit.
- **Check Bit (P)** : The check bit can be configured as 1-bit even parity, 1-bit odd parity, or no check bit.
- **Stop Bit (SP)** : The stop bit is fixed at high level and can be configured as 1 bit or 2 bits.

### 29.3.2.3 Modem Operation

Modem operations include the CTS function and RTS function. When USARTn\_CR3.RTSE=1, the RTS Function is Enabled. When USARTn\_CR3.CTSE=1, the CTS Function is Enabled.

#### CTS Function

The CTS function controls data transmission via the input of the USARTn\_CTS pin. Data can only be transmitted when the USARTn\_CTS pin input is at low level. If the USARTn\_CTS input transitions to high level during transmission, the ongoing data transmission is unaffected.

#### RTS Function

The RTS function outputs a low level through the USARTn\_RTS pin to request the peer to transmit data.

The USARTn\_RTS pin outputs a low level when all of the following conditions are met:

- Receive Enable (USARTn\_CR1.RE=1) and not currently receiving data.
- No unread receive data is in the USARTn\_RDR.RDR Register.
- No reception errors occurred, including frame errors, parity errors, and overflow errors.

### 29.3.2.4 Transmitter

The transmitter can send 8-bit or 9-bit data, depending on the setting of the USARTn\_CR1.M bit.

When USARTn\_CR1.TE bit is set to 1, the data is serially output on the TX pin after writing transmit data. The corresponding clock pulses can be optionally output or not output on the USARTn\_CK pin.

The sequence for transmitting data is: Start Bit -> Data Bit (MSB/LSB) -> Check Bit (if present) -> Stop Bit.

The transmit data register (TDR) and the internal transmit shift register form a double-buffered structure, enabling continuous data transmission.

When transmitting data via the transmit data register empty interrupt or DMA, to ensure transmission accuracy, only one data write can be performed per request.

#### Transmit Data Setting Procedure

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Configure the pins required for UART operation;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 Registers;

- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** Enable the transmitter (USARTn\_CR1.TE=1). If the transmit data register empty interrupt is required, set USARTn\_CR1.TXEIE=1.
- Step7.** Wait for the transmit data register to be empty, write communication data to USARTn\_TDR.TDR, data is transferred to the transmit shift register, transmission starts;

**Note**

When the CTS function is enabled, data is transferred to the transmit shift register and transmission starts when the USARTn\_CTS input is at Low level.

- Step8.** To continuously transmit data, repeat7;
- Step9.** Check whether the transmission is complete by verifying the USARTn\_SR.TC bit. For continuous data transmission using transmit interrupts, the last data can be written via the TI interrupt by setting USARTn\_CR1.TXEIE to 0 and USARTn\_CR1.TCIE to 1. A transmit completion interrupt will be generated after the last frame transmission ends.

Figure 29-3 UART Transmit Data Diagram 1

Figure 29-4 UART transmit Data Diagram 2

## Transmitter Interrupt

In UART Mode, the transmitter supports two interrupts: transmit data register empty interrupt (TI) and transmit completion interrupt (TCI).

- TXEIE=1, when the value of USARTn\_TDR.TDR register is transferred to the transmit shift register, a TI Interrupt is generated.
- TCIE=1, when the last bit of transmitted data is sent and the USARTn\_TDR.TDR register is not updated, a TCI interrupt is generated.

### 29.3.2.5 Receiver

The receiver can receive 8-bit or 9-bit data, depending on the setting of the USARTn\_CR1.M bit. After the receiver enable bit (USARTn\_CR.RE) is set to 1 and the start bit is detected, the data on the RX pin is received into the receive shift register. Once a complete frame of data is received, the data is transferred from the receive shift register to the receive data register USARTn\_RDR.RDR.

The sequence for receive data is: start bit -> data bit (MSB/LSB) -> check bit (present or absent) -> stop bit.

The receive data register USARTn\_RDR.RDR and the internal receive shift register form a double-buffered structure, enabling continuous data reception.

When receiving data through the receive data register full interrupt or DMA, only one data read operation can be performed per request.

## Start Bit Detection

Start bit detection can be configured for either low level or falling edge detection, determined by the USARTn\_CR1.SBS bit. When USARTn\_CR1.SBS=0, low level detection is selected; when USARTn\_CR1.SBS=1, falling edge detection is selected.

## Sampling and Reception Tolerance

Upon detecting a start condition (low level or falling edge), the USART synchronizes the receive data with the internal basic clock to initiate data reception.

Data sampling occurs at the center of the data. When USARTn\_CR1.OVER8=0, sampling is performed on the 8th internal basic clock; when USARTn\_MR.OVER8=1, sampling is performed on the 4th internal basic clock.

Figure 29-5 USART Internal Synchronization and Sample Timing

The UART asynchronous receiver can only operate normally when the total clock system deviation is less than the tolerance of the UART receiver. Factors affecting the total deviation include:

- Deviation caused by transmitter error (including the deviation of the transmitter local oscillator)
- Error caused by baud rate quantization of the receiver
- Deviation of the receiver local oscillator
- Deviation caused by transmission line

For correct receive data, the maximum deviation value allowed by the USART asynchronous receiver depends on the following options:

- Data length FL (Frame Length). FL is determined by the 8 or 9 data bits defined by the USART\_CR1.M bit and the parity enable bit defined by the PCE bit.
- The oversampling ratio (8x or 16x) is defined by the USART\_CR1.OVER8 bit.
- The USART\_CR1.FBME bit defines whether to use fractional baud rate.

Table 29-3 Tolerance of USART Receiver

| FL | DIV_Fraction is 0 |             | DIV_Fraction is not 0 |             |
|----|-------------------|-------------|-----------------------|-------------|
|    | OVER8 Bit=0       | OVER8 bit=1 | OVER8 bit=0           | OVER8 bit=1 |
| 10 | 4.375%            | 3.75%       | 3.88%                 | 3%          |
| 11 | 3.97%             | 3.41%       | 3.53%                 | 2.73%       |
| 12 | 3.646%            | 3.125%      | 3.23%                 | 2.5%        |

#### Note

Under special circumstances, when the RX pin receives continuous high level signals for the duration of FL, the data specified in the above table may vary slightly.

### Receive Data Setting Procedure

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Configure the pins required for UART operation;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** Enable the receiver (USARTn\_CR1.RE=1). If receive interrupt is required, set USARTn\_CR1.RIE=1.
- Step7.** Upon detecting the start bit, the receiver loads the data into the receive shift register and verifies the check bit and stop bit.
  - When a parity error occurs, the received data is transferred to the USARTn\_RDR.RDR register and the USARTn\_SR.PE flag is set.
  - When the stop bit is not at a high level, a frame error occurs. The received data is transferred to the USARTn\_RDR.RDR register, and the USARTn\_SR.FE flag is set.
  - When an overflow error occurs, data is lost and the USARTn\_SR.ORE flag is set.
  - When no error occurs, the received data is transferred to the USARTn\_RDR.RDR register, and the USARTn\_SR.RXNE flag is set. By repeating 7 after reading the received data, continuous data reception can be achieved.

Figure 29-6 UART Receive Data Diagram 1

Figure 29-7 UART Receive Data Diagram 2

## Error Handling

During data reception, there are three types of receive errors: overflow error (USARTn\_SR.ORE), parity error (USARTn\_SR.PE), and frame error (USARTn\_SR.FE). If any type of reception error occurs, data reception is disabled. To restart data reception, all error flags can be cleared by writing to the corresponding clear register.

The condition for overflow error occurrence is when a new frame of data is received while the USARTn\_RDR.RDR register value remains unread. Therefore, the previously received frame data should be read before the last bit of the current frame is received.

The condition for check error occurrence is when a parity check error happens.

The condition for frame error occurrence is when the stop bit is at low level. For 2-stop-bit cases, only the first stop bit is checked.

When an overflow error occurs, the received data is lost and no RI interrupt is generated.

When a parity error occurs, the received data is transferred to USARTn\_RDR.RDR, and no RI interrupt is generated.

When a frame error occurs, the received data is transferred to USARTn\_RDR.RDR, and no RI interrupt is generated.

## Receiver Interrupt

The USART Mode receiver supports two types of interrupts: receive data register full interrupt (RI) and error interrupt (EI).

- USARTn\_CR.RIE=1, when no receive error occurs and data is transferred from the receive shift register to the receive data register, an RI interrupt is generated.
- USARTn\_CR.RIE=1, when an overflow error, parity error, or frame error occurs during reception, an EI interrupt is generated.

### 29.3.2.6 UART Receive TIMEOUT Function

The TIMEOUT Counter starts when the UART Receive Data stop bit is detected. If the next frame of Receive Data is not detected after the configured TIMEOUT period (set in units of receive bits), a TIMEOUT occurs. If CR1.RE=1 at this time, the TIMEOUT status bit USARTn\_SR.RTOF is set. If USARTn\_CR1.RE=0, the USARTn\_SR.RTOF bit will be set after USARTn\_CR1.RE becomes 1.

The TIMEOUT counter utilizes the counter of the Timer0 module, the Timer0 counting mode must be configured as asynchronous count clock mode, with the asynchronous count clock source set to XTAL32 (the Timer0 count clock is provided by the clock tick generated from the UART Baud Rate Generator, and an XTAL32 crystal may not be required). The specific correspondence is as follows:

| USART1                | USART2                | USART3                | USART4                | USART5                | USART6                | USART7                | USART8                | USART9                | USART10               |
|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| Timer0_1<br>Channel A | Timer0_1<br>Channel B | Timer0_3<br>Channel A | Timer0_3<br>Channel B | Timer0_4<br>Channel A | Timer0_2<br>Channel A | Timer0_2<br>Channel B | Timer0_4<br>Channel B | Timer0_5<br>Channel A | Timer0_5<br>Channel B |

### TIMEOUT Function Timer0 Compare Counter Value Setting

Timer0 is a 16-bit counter. The maximum count clock frequency division selectable is 1024. The TMR0\_CMPA<B>R value setting calculation formula is as follows:

$$\text{CMPA<B>R} = \frac{\text{RTB}}{2^{\text{CKDIVA<B>}}} - \alpha$$

Where:

- CMPA<B>R: TMR0\_CMPA<B>R register value, round up the calculation result to the nearest integer.
- $\alpha$ : Delay caused by the Timer0 asynchronous counting synchronization circuit  
 When the count clock is not divided,  $\alpha=7$ ;  
 When the count clock is divided by 2,  $\alpha=5$ ;  
 When the count clock is divided by 4, 8, or 16,  $\alpha=3$ .  
 When the count clock frequency division is 32 or above,  $\alpha=2$ .
- RTB: Receive Timeout Bits, minimum value=Receive Data Frame length +  $\alpha \times 2^{\text{CKDIVA<B>}}$   
 The actual TIMEOUT occurrence time has a certain deviation from the RTB value, with an error  $\leq 2^{\text{CKDIVA<B>}}$ .
- CKDIRA<B>: TMR0\_BCONR.CKDIVA<B> bit register value

### TIMEOUT Function Setting Procedure

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Configure the pins required for UART operation;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bits (if the internal clock source is selected, set CR2.CLKC=0b01).
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 Registers;

- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** USARTn\_CR1.RTOE=1. If interrupts are required, set USARTn\_CR1.RTOIE=1.
- Step7.** Set TMR0\_BCONR.CSTA<B>=0;
- Step8.** Set TMR0\_CNTR<B>R to 0, configure the TMR0\_CMPA<B>R register and TMR0\_BCONR.CKDIVA<B> register to determine the TIMEOUT period;
- Step9.** Set TMR0\_BCONR.HCLEA<B>=1, TMR0\_BCONR.HSTAA<B>=1, TMR0\_BCONR.ASYNCLKA<B>=1, TMR0\_BCONR.SYNCLKA<B>=0, TMR0\_BCONR.SYNSEA<B>=1;
- Step10.** Enable the receiver (USARTn\_CR1.RE=1). If receive interrupt is required, set USARTn\_CR1.RIE=1.
- Step11.** Upon detecting TIMEOUT, follow these steps to disable the TMR0 timer and clear the USARTn\_SR.RTOF bit.  
Set both TMR0\_BCONR.SYNCLKA<B>=1 and TMR0\_BCONR.SYNA<B>=0, then simultaneously set TMR0\_BCONR.CSTA<B>=0, TMR0\_BCONR.SYNCLKA<B>=0, and TMR0\_BCONR.SYNSEA<B>=1. Clear the USARTn\_SR.RTOF bit by writing to USARTn\_CR1.CRTOF.

### 29.3.2.7 RX Line Wake-up Stop Mode Function

When the UART communication is idle, the system can enter Stop mode to reduce current consumption. Without altering the UART PORT settings, UART Unit 1 can wake up the system from Stop mode via the RX line. The specific steps are as follows:

- Step1.** When UART communication is idle, set the USART\_1\_WUPI interrupt vector and enable the UART receive signal line wake-up Stop mode function by setting the INTC\_WKEN.RXWKEN bit.
- Step2.** The system enters Stop mode;
- Step3.** When the system detects a falling edge on the RX line, it exits Stop mode and disables this function in the USART\_1\_WUPI interrupt handler.

Please note that when the communication party needs to wake up the system, it should send a wake-up frame (recommended as 0x00). This data will not be received by UART and will not set the related flag. Additionally, the communication party must wait for the wake-up time required by the system Stop Mode before initiating UART communication data transmission.

UART RX line wake-up function can filter noise on the RX line. For details, refer to the [USART\\_NFC Register](#).

### 29.3.2.8 UART Half-duplex Communication Mode

UART mode supports single-wire half-duplex operation. In UART mode, single-wire half-duplex mode is enabled by setting USARTn\_CR3.HDSEL=1.

In single-wire half-duplex mode:

- The TX and RX lines are internally connected, and the RX pin is no longer used.
- When there is no data transmission and the TX function is disabled, the TX pin is in a released state. Therefore, when using the single-wire half-duplex mode, the TX line is pulled up to prevent floating input when no data is being transmitted.
- When there is no data transmission and the transmit function is enabled, the TX pin outputs a high level.

In addition, the half-duplex mode is similar to communication in normal UART mode. Please note that the transmission process will not be blocked by hardware. As long as data is written when

USARTn\_CR1.TE=1, the transmission will proceed. Therefore, conflicts on the line must be managed by software.

In half-duplex communication, to prevent the UART from receiving its own transmitted data, it is recommended to set USARTn\_CR1.RE=0.

Figure 29-8 Half-Duplex Operation Timing

### 29.3.2.9 RS485 Driver Enable Function

UART Mode supports driver enable mode, sharing the output signal with RTS. First configure USART\_CR3.DEM to 1, then set USART\_CR3.RTSE to 1.

By setting the USART\_CR3.DEM to enable the driver function, users can activate external transceiver control through the DE (Driver Enable) signal. The assertion time programmed by the USART\_CR3.DEA is the time between DE signal activation and the start of the START bit.

Figure 29-9 OVER8=1 DE Asserted

Figure 29-10 OVER8=0 DE Asserted

The de-assertion time programmed by the USART\_CR3.DED is the duration between the end of the last stop bit and the DE signal deactivation. The polarity of the DE signal can be configured using the USART\_CR3.DEP.

Figure 29-11 OVER8=1 DE De-assertion

Figure 29-12 OVER8=0 DE De-assertion

### 29.3.2.10 Interrupt and Events

Table 29-5 UART Interrupt/Event Table

| Function Name           | Enable Bit (Interrupt only) | Flag Bit    | Used as Event Source |
|-------------------------|-----------------------------|-------------|----------------------|
| Receive Error Interrupt | RIE                         | ORE, FE, PE | Enable               |

| Function Name                          | Enable Bit (Interrupt only) | Flag Bit | Used as Event Source |
|----------------------------------------|-----------------------------|----------|----------------------|
| Receive Data Register Full Interrupt   | RIE                         | RXNE     | Enable               |
| Transmit Data Register Empty Interrupt | TXEIE                       | TXE      | Enable               |
| Transmit Completion Interrupt          | TCIE                        | TC       | Enable               |
| Transmit Completion Interrupt          | TENDIE                      | TEND     | Enable               |
| TIMEOUT Interrupt                      | RTOIE                       | RTOF     | Enable               |
| RX Line Wake-up Stop Mode Interrupt    | INTC_WKEN.RXWKEN            | -        | Disable              |

### 29.3.3 Multiprocessor Communication

#### 29.3.3.1 Function Introduction

Multiprocessor communication mode refers to a communication method where multiple processors share a common communication line. The processors are divided into Transmit Stations and Receive Stations, with each Receive Station having its own unique ID. The types of data transmitted by the Transmit Station include Receive Station ID and communication data. By adding the MPB bit in the Data Format, it distinguishes whether the current transmission is the Receive Station ID or communication data. When the MPB bit is 0, the current frame contains communication data; when the MPB bit is 1, the current frame carries the Receive Station ID. All Receive Stations can receive the ID sent by the Transmit Station and compare it with their own ID. If they match, the Receive Data is accepted; otherwise, the station enters Silent Mode (neither receiving data nor setting related Receive Flags) until the next ID is received.

Figure 29-13 Multiprocessor Communication Legend

#### 29.3.3.2 Data Format

Figure 29-14 Multiprocessor Mode Data Format

- **Start Bit (ST)** : The start bit is always composed of one bit at low level.
- **Data Bit (D)** : The data bit can be configured as 8-bit or 9-bit.
- **Multiprocessor bit (MPB)** : The multiprocessor bit can be configured to transmit communication data or send IDs.

- **Stop Bit (SP)** : The stop bit is fixed at high level and can be configured as 1 bit or 2 bits.

### 29.3.3.3 Action Description

In multiprocessor mode, the check bit has no effect, and the multiprocessor bit is added. Other functions such as clock and interrupt remain the same as in UART Mode.

#### Transmit Station Action

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Set the required pins to be used;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 Registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** Enable the transmitter (USARTn\_CR1.TE=1). If the transmit data register empty interrupt is required, set USARTn\_CR1.TXEIE=1.
- Step7.** Wait for the transmit data register to be empty, set USARTn\_TDR.MPID bit to 1 (Transmit ID), write the ID value to USARTn\_TDR, and transmit the ID.

**Note**

When the CTS function is enabled, data is transferred to the transmit shift register and transmission starts when the USARTn\_CTS input is at low level.

- Step8.** Set USARTn\_TDR.MPID bit to 0 (transmit data), write data to USARTn\_TDR to transmit data;

**Note**

When the CTS function is enabled, data is transferred to the transmit shift register and transmission starts when the USARTn\_CTS input is at low level.

- Step9.** If continuous data transmission is required, repeat step 8. If the ID needs to be changed before transmitting data, repeat steps 7 and 8.
- Step10.** Check whether the transmission is complete by verifying the USARTn\_SR.TC bit. For continuous data transmission using transmit interrupts, the last data can be written via the TI interrupt by setting USARTn\_CR1.TXEIE to 0 and USARTn\_CR1.TCIE to 1. A transmit completion interrupt will be generated after the last frame transmission ends.

Figure 29-15 Multiprocessor Mode Transmit Data Diagram

### Receive Station Action

In multiprocessor mode, the receive station must ensure it receives every ID data and compares it with its own ID. If they match, it receives the data; otherwise, it enters silent mode (neither receiving data nor setting receive-related flags) until the next ID data is received. This function is implemented via the USARTn\_CR1.SLME bit.

When USARTn\_CR1.SLME=0, receive data normally.

When USARTn\_CR1.SLME=1, unless data with the MPB bit set to 1 (ID) is received, receive data is disabled, no RI interrupt occurs, and error flags FE and ORE are not set. When data with the MPB bit set to 1 (ID) is received, the USARTn\_CR1.SLME bit is automatically cleared, enabling normal receive data and interrupt generation.

Action steps:

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Set the required pins to be used;
- Step3.** Select the clock source via the USARTn\_CR1.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 Registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** USARTn\_CR1.RE=1, USARTn\_CR1.SLME=1 (waiting to receive ID). If using receive interrupt, set USARTn\_CR1.RIE=1.
- Step7.** When the start bit is detected, the receiver loads the data into the receive shift register and checks the USARTn\_SR.MPB bit.
- Step8.** If USARTn\_SR.MPB=1, the USARTn\_CR1.SLME bit is automatically cleared, Receive Data normally, and the software compares the received ID with its own ID.
  - a. If the ID matches, receive data normally, an interrupt occurs, and error detection is performed, which is the same as UART receive data.
  - b. If the ID does not match, the software writes the USARTn\_CR1.SLME bit to 1 again and repeats step 8.

Figure 29-16 Multiprocessor Mode Receive Data Diagram 1

Figure 29-17 Multiprocessor Mode Receive Data Diagram 2

### 29.3.3.4 Interrupt and Events

In multiprocessor mode, the interrupt handling is identical to UART mode except for the absence of parity errors.

Table 29-6 Multiprocessor Mode Interrupt/Event Table

| Function Name                          | Enable Bit (Interrupt only) | Flag    | Used as Event Source |
|----------------------------------------|-----------------------------|---------|----------------------|
| Receive Error Interrupt                | RIE                         | ORE, FE | Enable               |
| Receive Data Register Full Interrupt   | RIE                         | RXNE    | Enable               |
| Transmit Data Register Empty Interrupt | TXEIE                       | TXE     | Enable               |
| Transmit Completion Interrupt          | TCIE                        | TC      | Enable               |

| Function Name                 | Enable Bit (Interrupt only) | Flag | Used as Event Source |
|-------------------------------|-----------------------------|------|----------------------|
| Transmit Completion Interrupt | TENDIE                      | TEND | Enable               |

### 29.3.4 UART-LIN

#### 29.3.4.1 Function Introduction

LIN stands for Local Interconnect Network, a low-speed (1-20kbps) serial communication protocol designed to reduce automotive network costs.

#### 29.3.4.2 LIN Data Format

A LIN frame consists of start bit + 8-bit data + 1 stop bit, with data transmitted and received in LSB format. The data behavior on the LIN Bus is as shown in the following figure.

Figure 29-18 LIN Bus Data Behavior

#### 29.3.4.3 LIN Transmit

##### Wake-up Signal Frame Transmit

Transmit the corresponding signal frame by transmitting data 0x80.

##### Interval Segment Transmit

The synchronous interval segment indicates the start of a frame. This product supports hardware transmission of the LIN interval segment.

The width of the low level in the LIN interval segment is determined by the USARTn\_CR2.SBK register setting.

- When USARTn\_CR2.SBKM=0, writing 1 to USARTn\_CR2.SBK will cause the hardware to automatically send out the interval segment.
- When USARTn\_CR2.SBKM=1, after writing 1 to USARTn\_CR2.SBK, writing data 0x00 to the transmit data register USARTn\_TDR.TDR starts transmitting the interval segment.

After the interval segment transmission is completed, USARTn\_CR2.SBK is automatically cleared.

##### Synchronization Segment Transmit

Transmit data 0x55 to achieve the transmission of the synchronization segment.

##### Bus Error Detection

When USARTn\_CR2.BEE=1, the USARTn\_SR.BE flag is set if the hardware detects a mismatch between the data on the bus and the transmitted data. When USARTn\_CR2.BEIE=1, the corresponding interrupt is generated.

#### 29.3.4.4 LIN Receive

##### Wake-up Signal Frame Detection

When USARTn\_CR2.WKUPE=1, the hardware automatically detects the wake-up signal. Upon detecting a low-level width on the RX line greater than or equal to 2.5 bit data widths (130μs at 19.2kbps), the

USARTn\_SR.WKUP flag is set. When USARTn\_CR2.WKUPE=1, the corresponding interrupt is generated. Upon detecting a wake-up signal frame, clear the USARTn\_SR.WKUP flag and read the USARTn\_RDR.RDR register.

The USARTn\_CR2.WKUPE register should be set to 1 only when the system needs to wait for a wake-up signal; otherwise, it must be set to 0.

### Synchronous Interval Segment Detection

This product supports hardware-based synchronous interval segment detection. When the low-level width on the communication line is greater than or equal to the value set in the USARTn\_CR2.LBDL register and a break delimiter is detected, the USARTn\_SR.LBD flag is set. When USARTn\_CR2.LBDIE=1, the corresponding interrupt is generated.

Note that during synchronous interval segment detection, the USARTn\_SR.FE flag will be set. While clearing the USARTn\_SR.LBD flag, the USARTn\_SR.FE flag must also be cleared, and the USARTn\_RDR.RDR register should be read (the read value is 0x00).

### Synchronization Segment Detection and Baud Rate Measurement

Upon detecting the interval segment, the hardware automatically measures the frequency of the synchronization segment. The clock for measuring the counter is set by the USARTn\_PR.LBMPSC bit. The counter value is stored in the USARTn\_LBMC register. The baud rate of the master node can be obtained by dividing the selected counter clock frequency by the value in the USARTn\_LBMC register.

Please note that reading the USARTn\_LBMC register must be performed after the synchronization segment reception is completed.

### Receive Data Setting Procedure

- Step1.** Set the USARTn\_CR1 register to its reset value;
- Step2.** Configure the pins required for UART operation;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1 (RE=1, RIE=0), USARTn\_CR2, and USARTn\_CR3 registers.
- Step5.** (Optional) wake-up signal frame detection:
  - a. Set USARTn\_CR2.WKUPE=1 and wait for the wake-up signal;
  - b. Wake-up signal detected, USARTn\_CR2.WKUPE=0, waiting for synchronization segment interval segment.
- Step6.** (Optional) synchronization segment interval field detection:
  - a. Upon detecting a break in the sync interval, clear the USARTn\_SR.FE/LBD flag and verify that the received data is 0x00.
- Step7.** (Optional) Synchronization segment frequency measurement and communication Baud rate calculation:
  - a. To use the receive interrupt, set USARTn\_CR1.RIE=1.
  - b. Upon detecting the synchronization gap field and completing the reception of the synchronization segment, read the USARTn\_LBMC register to calculate the baud rate. If the received data is 0x55, it indicates the baud rate error is within the acceptable range. If the received data is not 0x55, user calibration of the baud rate is mandatory. The user should recalibrate the baud rate based on the USARTn\_LBMC register.
- Step8.** Receive identification segment (process is the same as UART receive data process);
- Step9.** Receive Data (process is the same as UART receive data process);
- Step10.** Receive checksum (process is the same as UART receive data process).

### 29.3.4.5 Interrupt and Events

Table 29-7 LIN Interrupt/Event Table

| Function Name                                       | Enable Bit (Interrupt only) | Flag Bit | Used as Event Source |
|-----------------------------------------------------|-----------------------------|----------|----------------------|
| Error Interrupt                                     | RIE                         | ORE, FE  | Enable               |
|                                                     | BEIE                        | BE       | Enable               |
| Wake-up Signal/Interval Segment Detection Interrupt | WKUPIE                      | WKUP     | Enable               |
|                                                     | LBDIE                       | LBD      | Enable               |
| Receive Data Register Full Interrupt                | RIE                         | RXNE     | Enable               |
| Transmit Data Register Empty Interrupt              | TXEIE                       | TXE      | Enable               |
| Transmit Completion Interrupt                       | TCIE                        | TC       | Enable               |
| Transmit Completion Interrupt                       | TENDIE                      | TEND     | Enable               |

### 29.3.5 Smart Card

#### 29.3.5.1 Connection Schematic Diagram

Supports the smart card communication protocol specified in ISO/IEC 7816-3. The figure below shows the connection schematic diagram for smart card mode.

Figure 29-19 Smart Card Connection Schematic Diagram

#### 29.3.5.2 Clock

##### Internal Clock Source

In smart card mode, only the clock generated by the internal baud rate generator can be used as the clock source.

The basic number of clock periods for 1-bit data transmission is determined by the USARTn\_CR3.BCN setting.

The clock output in smart card mode is controlled by setting the USARTn\_CR2.CLKC bit in the register.

##### Maximum Baud Rate

When the internal clock source is selected, the baud rate generated by the internal baud rate generator is calculated using the following formula:

$$B = \frac{C}{2 \times BCN \times (DIV\_Integer + 1)}$$

Where:

- B: Baud rate, unit: Mbps
- C: When USARTn\_PR.ULBREN is 0, the clock set by USARTn\_PR.PSC bit (PCLK1, PCLK1/4, PCLK1/16, PCLK1/64), unit: MHz  
When USARTn\_PR.ULBREN is 1, the clock set by USARTn\_PR.PSC bit (PCLK1/128, PCLK1/256, PCLK1/512, PCLK1/1024), unit: MHz
- DIV\_Integer: USARTn\_BRR.DIV\_Integer setting value
- BCN: USARTn\_CR3.BCN register setting value

When C is PCLK1, DIV\_Integer=0, and BCN=0, the baud rate reaches the maximum baud rate of PCLK1/64 (Mbps).

### Sampling and Reception Tolerance

Upon detecting the falling edge of RX, the USART synchronizes the receive data with the internal basic clock to initiate data reception. The receive data will be sampled at the center of the data.

Figure 29-20 Smart Card Mode Synchronization Timing and Sample Timing Diagram

Receive tolerance calculation formula:

$$RM = \{0.5 \times (1 - \frac{1}{BCN}) - 9.5CFD\} \times 100\%$$

Where:

- RM: Reception Margin
- BCN: Number of clocks required for 1 bit of data transmission (set by USARTn\_CR3.BCN)
- CFD: Clock Frequency Deviation

#### 29.3.5.3 Data Format

In smart card mode, a frame of data consists of start bit, data bit and check bit.

Figure 29-21 Smart Card Mode Data Format

- **Start Bit (ST)** : The start bit is always composed of one bit at low level.
- **Data Bit (D)** : The data bit is fixed as 8-bit data.
- **Check Bit (P)** : The check bit must be configured as 1-bit even parity.

#### 29.3.5.4 Initialization Setup Procedure for Smart Cards

- Step1.** Configure the USARTn\_CR1 register to the reset value;
- Step2.** Configure the required pins to be used;

- Step3.** Status register confirmed, USARTn\_SR register setting is reset to default value;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 Registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for the communication baud rate.
- Step6.** USARTn\_CR2.CLKC bits configure clock control;
- Step7.** Configuration of USARTn\_CR1 register (TE, RE, RIE, TXEIE bits) : Except for self-test, do not simultaneously set both TE and RE to 1.

When switching from transmit mode to receive mode, or from receive mode to transmit mode, steps 1 to 7 above must be reconfigured.

### 29.3.5.5 Smart Card Mode Action Description

In smart card mode, the flag bit for the TI interrupt (transmit data empty interrupt) is the USARTn\_SR.TC bit. A TI interrupt is generated when USARTn\_SR.TC=1 and USARTn\_CR1.TXEIE=1.

#### Function Overview

During data transmission, there must be a protection time of at least 2etu (Elementary Time Unit) between two frames (from the end of the check bit to the start of the next frame's start bit).

If an error signal from the receiver is detected during data transmission, the data will be automatically retransmitted after 2etu.

When a parity error occurs in the received data, a low-level error signal is transmitted for 1etu. The error signal is sent with a timing of 10.5 etu after the start of reception.

#### Transmission Instructions

After a frame of data is transmitted, if an error signal from the receiver is detected, USARTn\_SR.FE is set to 1 (an error interrupt occurs if USARTn\_CR1.RIE=1). The USARTn\_SR.TC flag is not set, and the data is auto retransmitted. The USARTn\_SR.FE bit must be cleared before receiving the next frame's check bit.

After a frame of data is transmitted without errors, the USARTn\_SR.TC flag is set, and a TI interrupt occurs when USARTn\_CR1.TXEIE=1. Writing the data again enables continuous data transmission.

Figure 29-22 Smart Card Mode Transmit Data Diagram

## Receive Instructions

When receiving data, if a parity error is detected, USARTn\_SR.PE is set. When interrupt enable is active, an EI interrupt occurs. The USARTn\_SR.PE bit must be cleared before receiving the next frame's check bit.

When a parity error occurs, a low level of 1etu is transmitted as the error signal, requesting the sender to retransmit the data.

Normal receive data, the received data can be read via RI Interrupt, continuous reception.

Detect overflow error when receiving data.

Figure 29-23 Smart Card Mode Receive Data Diagram

### 29.3.5.6 Interrupt and Events

Table 29-8 Smart Card Mode Interrupt/Event Table

| Function Name                 | Enable Bit (Interrupt only) | Flag Bit    | Used as Event Source |
|-------------------------------|-----------------------------|-------------|----------------------|
| Error Interrupt               | RIE                         | ORE, PE, FE | Enable               |
| Receive Data Full Interrupt   | RIE                         | RXNE        | Enable               |
| Transmit Data Empty Interrupt | TXEIE                       | TC          | Enable               |

## 29.3.6 Clock Synchronization Mode

### 29.3.6.1 Clock

The clock synchronization mode can select either the clock generated by the internal baud rate generator (internal clock source) or the clock input from the USARTn\_CK pin (external clock source) as the communication clock source.

#### Internal Clock Source

The synchronization clock is output from the USARTn\_CK pin. A frame of data outputs 8 clock pulses. When neither transmitting nor receiving data, the clock output remains fixed at high level.

#### External Clock Source

The external clock source inputs the clock from the USARTn\_CK pin as the communication clock.

## Maximum Baud Rate

When the internal clock source is selected, the baud rate generated by the internal baud rate generator is calculated using the following formula:

$$B = \frac{C}{4 \times (\text{DIV\_Integer} + 1)}$$

Where:

- B: Baud rate, unit: Mbps
- C: When USARTn\_PR.ULBREN is 0, the clock set by USARTn\_PR.PSC bit (PCLK1, PCLK1/4, PCLK1/16, PCLK1/64), unit: MHz  
When USARTn\_PR.ULBREN is 1, the clock set by USARTn\_PR.PSC bit (PCLK1/128, PCLK1/256, PCLK1/512, PCLK1/1024), unit: MHz
- DIV\_Integer: USARTn\_BRR.DIV\_Integer setting value

When the internal clock source is selected and C is PCLK1 with DIV\_Integer=1, the maximum baud rate is PCLK1/8 (Mbps).

### Notice

In synchronous mode, setting DIV\_Integer to 0 is prohibited.

When using an external clock source, the maximum frequency requirement for the external input clock is PCLK1/6 (MHz), so the maximum baud rate is PCLK1/6 (Mbps).

Please note that in synchronous mode, the maximum communication baud rate is not only determined by the PCLK1-based calculation method described above but also needs to refer to the maximum communication baud rate specified in the "Electrical Specifications" chapter of the Datasheet.

### 29.3.6.2 Data Format

In clock synchronization mode, each frame of data consists of a fixed 8 bits. The transmission and reception of one frame requires 8 synchronization clock pulses. During data transmission, data is sent on the falling edge of the synchronization clock. During data reception, data is sampled on the rising edge of the synchronization clock.

The synchronization clock remains fixed at high level when there is no data transmission. After the last bit is transmitted, the communication line maintains the value of the last bit.

Figure 29-24 Clock Synchronization Mode Data Format

### 29.3.6.3 Modem Operation

Modem operations include the CTS function and RTS function. When USARTn\_CR3.RTSE=1, the RTS function is enabled. When USARTn\_CR3.CTSE=1, the CTS function is enabled.

#### CTS Function

The CTS function controls data transmission via the input of the USARTn\_CTS pin. Data can only be transmitted when the USARTn\_CTS pin input is at low level. If the USARTn\_CTS input transitions to high level during transmission, the ongoing data transmission is unaffected.

## RTS Function

The RTS function outputs a low level through the USARTn\_RTS pin to request the peer to transmit data.

The USARTn\_RTS pin outputs a low level when all of the following conditions are met:

- Receive enable (USARTn\_CR1.RE=1) and not currently receiving data
- There is no unread data in the USARTn\_RDR.RDR register (when USARTn\_CR1.RE=1)
- USARTn\_TDR.TDR update completed (when USARTn\_CR1.TE=1)
- No receiving errors

If all the above conditions cannot be met at the same time, USARTn\_RTS outputs a high level.

### 29.3.6.4 Transmitter

When USARTn\_CR1.TE bit is set to 1, the data in the transmit shift register is serially output at the USARTn\_TX pin, and the corresponding clock pulse is output at the USARTn\_CK pin.

The transmit data register USARTn\_TDR.TDR and the internal transmit shift register form a double buffer structure, which can transmit data continuously.

When transmitting data via the transmit data register empty interrupt or DMA, to ensure transmission accuracy, only one data write is enabled per request.

### Transmit Data Setting Procedure

- Step1.** Configure USARTn\_CR1, USARTn\_SR1 registers to reset values;
- Step2.** Configure the required pins to be used;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** Enable the transmitter (USARTn\_CR1.TE=1). If the transmit data register empty interrupt is required, set USARTn\_CR1.TXEIE=1.
- Step7.** Wait for the transmit data register to be empty, write communication data to USARTn\_TDR.TDR, data is transferred to the transmit shift register, transmission starts;

#### Note

When the CTS function is enabled, data is transferred to the transmit shift register and transmission starts when the USARTn\_CTS input is at low level.

- Step8.** To continuously transmit data, repeat step 7;
- Step9.** Check whether the transmission is complete by verifying the USARTn\_SR.TC bit. For continuous data transmission using transmit interrupts, the last data can be written via the TI interrupt by setting USARTn\_CR1.TXEIE to 0 and USARTn\_CR1.TCIE to 1. A transmit completion interrupt will be generated after the last frame transmission ends.

Figure 29-25 Data Transmission in Clock Synchronization Mode Diagram 1 (LSB/without CTS function)

Figure 29-26 Data Transmission in Clock Synchronization Mode Diagram 2 (LSB/with CTS function)

### Transmitter Interrupt

The clock synchronous mode transmitter supports two interrupts, the transmit data register empty interrupt TI and the transmit completion interrupt TCI.

- TXEIE=1, when the value of USARTn\_TDR.TDR register is transferred to the transmit shift register, a TI interrupt is generated.
- TCIE=1, when the last bit of transmitted data is sent and the USARTn\_TDR.TDR register is not updated, a TCI interrupt is generated.

#### 29.3.6.5 Receiver

##### Receive Data Setting Procedure

- Step1.** Configure USARTn\_CR1, USARTn\_SR registers to reset values;
- Step2.** Configure the required pins to be used;
- Step3.** Select the clock source via the USARTn\_CR2.CLKC bit;
- Step4.** Configure the USARTn\_CR1, USARTn\_CR2, and USARTn\_CR3 registers;
- Step5.** Set USARTn\_PR to select the prescaler value, and configure the USARTn\_BRR register for communication baud rate (no setting required when the clock source is an external clock source);
- Step6.** Enable the receiver (USARTn\_CR1.RE=1). If receive interrupt is required, set USARTn\_CR1.RIE=1.

#### Note

When using the RTS function, USARTn\_RTS outputs a low level after RE=1.

- Step7.** Start receiving data in synchronization with the input synchronization clock or the internally generated synchronization clock, and receive data into the receive shift register.

- When an overflow error occurs, data is lost and the USARTn\_SR.ORE flag is set;
- When no error occurs, the received data is transferred to the USARTn\_RDR.RDR register, the USARTn\_SR.RXNE flag is set, and the currently received data is read before the last bit of the next frame is received. Repeating step 7 can realize the continuous data reception function.

**Note**

When using the RTS function, USARTn\_RTS outputs a low level after data is read.

Figure 29-27 Data Reception in Clock Synchronization Mode Diagram 1 (LSB/without RTS function)

Figure 29-28 Data Reception in Clock Synchronization Mode Diagram 2 (LSB/with RTS function)

## Error Handling

When receiving data in clock synchronous mode, the reception error is an overflow error (USARTn\_SR.ORE). When a reception error occurs, data transmission and reception are halted. To resume data transmission, the error flags must be cleared by writing to the corresponding clear register.

The condition for an overflow error is that new data is received without reading the USARTn\_RDR.RDR value, so the data received in the previous frame should be read before the last bit of the current frame is received. When an overflow error occurs, the received data is lost and no RI interrupt is generated.

## Receiver Interrupt

The clock synchronous mode receiver supports two interrupts, the receive data register full interrupt RI and the receive error interrupt EI.

- When RIE=1, when data is transferred from the receive shift register to the receive data register, an RI interrupt is generated.
- When RIE=1, when a receive error (such as an overflow error) occurs during reception, an EI interrupt is generated.

### 29.3.6.6 Simultaneous Transmission and Reception

The USART synchronous clock mode supports full-duplex operation, enabling simultaneous data transmission and reception. To perform simultaneous transmission and reception, a command must set RE, TE, RIE, and TXEIE to 1. Other configuration procedures are the same as those for the transmitter and receiver individually.

### 29.3.6.7 Interrupt and Events

Table 29-9 Interrupt/Event Table in Synchronous Clock Mode

| Interrupt Name                         | Enable bit (Interrupt only) | Flag Bit | Used as Event Source |
|----------------------------------------|-----------------------------|----------|----------------------|
| Receive Error Interrupt                | RIE                         | ORE      | Enable               |
| Receive Data Register Full Interrupt   | RIE                         | RXNE     | Enable               |
| Transmit Data Register Empty Interrupt | TXEIE                       | TXE      | Enable               |
| Transmit Completion Interrupt          | TCIE                        | TC       | Enable               |
| Transmit Completion Interrupt          | TENDIE                      | TEND     | Enable               |

### 29.3.7 Digital Filter Function

When USARTn\_CR1.NFE=1, the built-in digital filter function is enabled. The digital filter is only active in UART mode and can remove noise on the receive data line RX.

The built-in digital filter can filter out noise with a width less than 3/16 (USARTn\_CR1.OVER8=0) or 3/8 width (USARTn\_CR1.OVER8=1) of 1 bit.

If the digital filter's clock stops and then starts again, the digital filter resumes operation from the state maintained when the clock stopped.

When USARTn\_CR.TE=0 and USARTn\_CR.RE=0, the Flip-Flop state inside the digital filter is reset to 1.

Enable Filtering, No Interference

Enable filtering, interference not filtered, no impact on sampling (when the sampling signal is valid, no interference signal is sampled)

Enable filtering, filter out interference, no impact on sampling (interference signals are filtered out, and correct signals are sampled)

Enable filtering, interference not filtered, affects sampling (interference not filtered out, interference signals are sampled)

Figure 29-29 Digital Filter Function Diagram

- rxd\_s1: internal signal RX delayed by 1 sampling clocks
  - rxd\_s2: internal signal RX delayed by 2 sampling clocks
  - rxd\_nf: the actual sampled signal, determined by comparing the input signal RX, rxd\_s1, and rxd\_s2.
- Enabling the NF (Noise Filter) function performs two delayed operations on the input RX signal, generating three signals in total. Only when the input signal matches both delayed signals can the internal module perform signal toggling.

## 29.3.8 Interrupt

Table 29-10 USART Global Interrupt Summary Table

| Interrupt Name                                      | Symbol                    | Description                                                                                                                                                                                      |
|-----------------------------------------------------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 29.4 Register Description

This chapter provides a detailed description of the USART module control status and related registers. The function register bit is only valid when the corresponding function is configured for the channel; otherwise, it defaults to 0.

### 29.4.1 Register List

USART1\_NFC base address: 0x40055400

Table 29-11 USART1 Filter Control Register Offset

| Offset | Register   | Description                    | Width |
|--------|------------|--------------------------------|-------|
| 0x1C   | USART1_NFC | USART1 Filter Control Register | 32    |

- USART1 base address: 0x4001CC00
- USART2 base address: 0x4001D000
- USART3 base address: 0x4001D400
- USART4 base address: 0x4001D800
- USART5 base address: 0x4001DC00
- USART6 base address: 0x40020C00
- USART7 base address: 0x40021000
- USART8 base address: 0x40021400
- USART9 base address: 0x40021800
- USART10 base address: 0x40021C00

Table 29-12 Universal Synchronous Asynchronous Receiver/Transmitter (USART) Register Offset

| Offset | Register   | Description                              | Width |
|--------|------------|------------------------------------------|-------|
| 0x00   | USART_SR   | Status Register                          | 32    |
| 0x04   | USART_TDR  | Transmit Data Register                   | 16    |
| 0x06   | USART_RDR  | Receive Data Register                    | 16    |
| 0x08   | USART_BRR  | Baud Rate Register                       | 32    |
| 0x0C   | USART_CR1  | Control Register 1                       | 32    |
| 0x10   | USART_CR2  | Control Register 2                       | 32    |
| 0x14   | USART_CR3  | Control Register 3                       | 32    |
| 0x18   | USART_PR   | Prescaler Register                       | 32    |
| 0x1C   | USART_LBMC | LIN Baud Rate Measurement Count Register | 32    |

## 29.4.2 Status Register (USART\_SR)

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |     |          |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |      |  |  |  |  |  |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|------|--|--|--|--|--|

## 29.5 Precautions

### 29.5.1 UART Precautions

#### Transmitter

When the transmitter is disabled in UART mode (USARTn\_CR1.TE=0), the TX pin can be used as a general-purpose I/O, allowing output value and direction configuration. If the output is 0, it will cause a frame error on the receiver side, thereby triggering an interrupt in data transmission. If the output is 1, the receiver cannot detect the start bit, thus preventing data transmission from starting.

#### Receiver

In UART mode, when a frame error occurs, software can detect whether the subsequent RX line is at a low level to determine if the sender intends to interrupt the transmission.

If the start bit detection mode for receive data is set to low level detection, continuing to receive all low level data after clearing the error flag will cause the receive error to occur again.

### 29.5.2 Clock Synchronous Mode Precautions

1. When using an external input clock for data transmission, the USARTn\_TDR.TDR register must be updated before the clock is applied. After writing data to the register, the clock input must be delayed by at least one bit time.
2. When transmitting data continuously, the next frame must be updated before the last bit of the current frame is transmitted.

### 29.5.3 Other Precautions

To prevent the TX communication line from entering Hi-Z state when transmission is disabled, the following methods can be adopted:

- Communication line pull-up;
- Before the end of data transmission and before USARTn\_CR1.TE=0, configure the TX pin as a general-purpose IO output.
- Before transmitting data starts, after USARTn\_CR1.TE=1, configure the IO as TX function.

## 30 Inter-Integrated Circuit (I2C)

### 30.1 Introduction

I2C (Inter-Integrated Circuit) used as an interface between the microcontroller and the I2C serial bus. Provide multi-master mode function, which can control the protocol and arbitration of all I2C buses. Standard mode and fast mode are supported. SMBus is also supported.

### 30.2 Features

- I2C bus mode and SMBUS bus mode are optional. Master mode and slave mode are optional. Automatically ensure various preparation times, hold times, and bus idle times corresponding to the transfer rate
- Standard mode up to 100kbps, fast mode up to 400kbps
- The start condition, restart condition, and stop condition are automatically generated, and the start condition, restart condition, and stop condition of the bus can be detected
- Supports up to 128 slave mode addresses. Supports 7-bit address format and 10-bit address format. Broadcast call address, SMBus host address, SMBus device default address, SMBus alarm address can be detected
- Answer bits can be automatically determined when sent. Answer bits can be automatically sent when reception
- Handshake function
- Arbitration function
- Timeout function, can detect SCL clock stop for a long time
- SCL input and SDA input have built-in digital filters that are programmable to filter
- Communication error, receive data full, send data empty, one frame send end, address match unani-mously interrupt
- 2-stage transmit FIFO and 2-stage receive FIFO

## 30.3 Functional Description

### 30.3.1 I2C System Block Diagram

Figure 30-1 I2C System Block Diagram

Figure 30-2 Example of I2C Bus Structure

Table 30-1 Input/Output Pin

| Pin Name | Input/Output | Function                         |
|----------|--------------|----------------------------------|
| SCL      | Input/Output | Input/output pin of serial clock |
| SDA      | Input/Output | Input/output pin of serial data  |

When the I2C bus is selected, the SCL/SDA input level is the Schmitt level (compatible with the CMOS level). When the SMBus is selected, please set the SCL/SDA input level to the CMOS level by setting PCRxy.CINSEL in "General-Purpose IO (GPIO) " "Register-General Control Register (PCRxy) ".

### 30.3.2 I2C Protocol

#### 30.3.2.1 Data Transmission

I2C bus consists of a clock line (SCL) and a data line (SDA). All connection devices must be drain open output. The SCL and SDA lines are connected to external pull-up resistors, and the resistance value depends on the system application.

In general, a complete communication process consists of the following four parts:

1. Start Condition
2. Address Transmission
3. Data Transmission
4. Stop Condition

Figure 30-3 I2C Bus Timing Diagram

#### Start Condition

When the master on the bus does not drive the bus, the bus enters the idle state. Both SCL and SDA are high level. Devices on the bus in idle state can start the communication by sending the start condition.

If the START position is set to 1 in the I2C\_SR.BUSY flag of 0 (bus is idle), the start condition is issued. If a start condition is detected, the I2C\_SR.BUSY flag and I2C\_SR.STARTF flag are automatically set to 1 and the START bit is automatically set to 0. At this point, if the status of the SDA signal sent in the START bit 1 is the same as that of the SDA line, and the start condition is detected, it is considered that the start condition is correctly issued by the START bit, and the I2C\_SR.MSL bit and I2C\_SR.TRA bit are automatically set to 1 and then changed to the master send mode. In addition, I2C\_SR.EMPTFYF

automatically changes to 1 because the TRA bit is 1. Next write the slave address to the I2C\_DTR register and send the address.

### Address Transmission

The frame after the start condition or restart condition is an address frame that specifies the object address for master communication. The specified slave is always enable until the stop condition is sent.

The top 7 bits of the address frame are the slave addresses. The eighth bit of the address frame determines the direction of the data frame.

1. The 7-bit addressing mode is shown in the following figure [7-bit address format]

Master send mode, master send address frame 8th bit is 0;

Master receive mode, master send address frame 8th bit is 1.

2. The 10-bit addressing mode is shown in the following figure [10-bit address format]

Master send mode, master first frame send header sequence (0b11110XX0, where XX represents the top two digits of the 10-bit address), then the second frame send the low eight-bit slave address.

Master receive mode, master first frame send header sequence (0b11110XX0, where XX represents the top two digits of the 10-bit address), and then the second frame send the low eight-bit slave address. Next, a restart condition is sent, and then a frame header sequence is sent (0b11110XX1, where XX represents the top two digits of the 10-bit address).

#### 7-bit Address Format

|   |             |          |              |              |     |              |              |   |
|---|-------------|----------|--------------|--------------|-----|--------------|--------------|---|
| S | SLA (7-bit) | R/<br>W# | ACK/<br>NACK | DATA (8-bit) | ACK | DATA (8-bit) | ACK/<br>NACK | P |
|---|-------------|----------|--------------|--------------|-----|--------------|--------------|---|

#### 10-bit Address Format

|   |                         |    |     |             |     |              |     |              |              |   |
|---|-------------------------|----|-----|-------------|-----|--------------|-----|--------------|--------------|---|
| S | 0b11110+SL<br>A (2-bit) | W# | ACK | SLA (8-bit) | ACK | DATA (8-bit) | ACK | DATA (8-bit) | ACK/<br>NACK | P |
|---|-------------------------|----|-----|-------------|-----|--------------|-----|--------------|--------------|---|

|   |                         |    |     |             |     |    |                         |   |     |              |     |              |              |   |
|---|-------------------------|----|-----|-------------|-----|----|-------------------------|---|-----|--------------|-----|--------------|--------------|---|
| S | 0b11110+SL<br>A (2-bit) | W# | ACK | SLA (8-bit) | ACK | Sr | 0b11110+SL<br>A (2-bit) | R | ACK | DATA (8-bit) | ACK | DATA (8-bit) | ACK/<br>NACK | P |
|---|-------------------------|----|-----|-------------|-----|----|-------------------------|---|-----|--------------|-----|--------------|--------------|---|

Figure 30-4 Data Format of I2C Bus

- S: Indicates the start condition
- SLA: Indicates the slave address
- RW#: Indicates the direction of transmission and reception. Send data from slave to master when RW# is 1; When RW# is 0 the data is sent from the master to the slave.
- Sr: Indicates the restart condition
- DATA: Indicates the data sent and received
- P: Indicates the stop condition

### Data Transmission

After address matching is consistent, the master on the bus transmits data frame by frame according to the direction defined by R/W.

The data transmitted after all address frames are treated as data frames. Even a low 8-bit address in a 10-bit address format is considered a data frame.

The length of the data frame is 8 bits. The low-level SDA of the SCL changes, the high-level SDA of the SCL remains, and a bit of data is sent per clock period. The 9th clock after the data frame is an answer bit and is a handshake signal transmitted to the receiver.

If data is received from the slave on the bus and does not respond to the master in the ninth clock period, the slave must send NACK. If the master receives data on the bus, NACK is sent in the 9th period, NACK is received from the slave, and data is stopped from the slave.

Whether the master or the slave sends NACK, the data transfer interrupts. The master can do any of the following:

1. Transmit stop condition to release bus;
2. Send the restart condition to start a new communication.

#### ● Master transmitting data

In master transmit mode, the master outputs SCL clock and transmit data, the slave receives data and returns an answer. The sequence of master sending data is shown in the following figure.

Figure 30-5 Sequence Diagram of Master Transmitting Data in 7-bit Address Format (Example)

#### ● Master receiving data

In master receiving mode, the master outputs an SCL clock, receives slave data, and returns an answer. The running sequence of receiving data by the master is shown in the following figure.

Figure 30-6 Sequence Diagram of Master Receiving Data in 7-bit Address Format (Example)

- Slave transmitting data

In slave send mode, the SCL clock from the master is received. This product sends data for the slave and receives a reply from the master. The sequence of data sent from the slave is shown in the following figure.

Figure 30-7 Sequence Diagram of Slave Transmitting Mode in 7-bit Address Format (Example)

### ● Slave receiving data

In slave receiving mode, the SCL clock and data from the master are received, and the response is returned after receiving the data. The sequence of data received from the slave is shown in the following figure.

Figure 30-8 Sequence Diagram of Slave Receiving Data in 7-bit Address Format (Example)

### Stop Condition

A stop condition is sent via the I2C\_CR1.STOP bit.

When the I2C\_SR.BUSY flag is 1 (bus is busy) and the I2C\_SR.MSL bit is 1 (master mode), the STOP bit is set to 1 to issue a stop condition.

### Restart Condition

Through I2C\_CR1.RSTART bit generation restart condition.

The RSTART bit 1 generates a restart condition when the I2C\_SR.BUSY flag is 1 (busy bus) and the I2C\_SR.MSL bit is 1 (master mode).

By restarting the condition, the master can switch transmit/receive modes without releasing BUS authority. Communication can also be established with another slave without releasing BUS authority.

#### 30.3.2.2 SCL Clock Synchronization

When using the I2C bus in multi-master mode, there is a possibility that the SCL clock may conflict due to competition with other masters. If the SCL clock conflicts, the master needs to synchronize with the SCL clock and synchronize the SCL clock bit by bit. When the rising edge of the SCL line is detected and the high level set by I2C\_CCR.SHIGHW register is counted, if the SCL line is lowered due to the SCL clock output of other masters, the increment count of the high level width is stopped when the falling edge of the SCL line is detected, and the increment count of the low level width set by I2C\_CCR.SLOWW is started while the SCL line is driven to low level. When the counting of the low-level width ends, the low-level drive of the SCL line is terminated and the SCL line is released. At this time, if the low level width of the SCL clock of other masters is greater than the low-level width set by SLOWW, the low-level width of the SCL clock is prolonged. When other masters end the low-level output, release the SCL line

and the SCL clock rises. Therefore, in case of SCL clock output conflict, the high level width of SCL clock synchronizes with short clock, and the low level width synchronizes with long clock.

Figure 30-9 SCL Synchronous Timing

### 30.3.2.3 Arbitration

I2C bus is a real multi-master bus that allows multiple masters to connect.

If two or more masters try to control the bus at the same time, the SCL clock synchronization process determines the bus clock. The low period of the bus clock depends on the longest low-level clock and the high period depends on the shortest high-level clock. The results of arbitration are determined by the data collected at high levels. When the SDA output sent is a high-level output (the SDA pin is in a high impedance state) and the SDA line is detected to be at a low-level, arbitration fails. The I2C\_SR.AROLF bit will be set to "1" by hardware. If a master arbitration fails, it is immediately transferred to the slave receiving mode. At this point, if the slave addresses matches, including broadcast addresses, the slave mode continues to run.

### 30.3.2.4 Handshake

The handshake is realized by SCL clock synchronization mechanism during data transfer. After transmitting a frame of data (including ACK bits), the slave maintains the SCL clock line at low level. In this case, the low level of the SCL clock causes the master to enter the waiting state until the SCL line is released from the slave.

### Slave Transmitting Mode

In the transmitting mode (I2C\_SR.TRA bit=1), if the internal shift register is empty and the transmitting data (I2C\_DTR register) is not written, the SCL line is automatically kept low in the low level interval between the 9th clock and the 1st clock of the next transmission. The action timing is shown in the figure below.

Figure 30-10 Transmitting Timing Diagram of Slave (1)

After the I2C\_SR.NACKF flag is changed to 1 or the last sent data is written to the I2C\_DTR register, wait until the I2C\_SR.TENDF flag changes to 1 while the I2C\_SR.EMPTFYF flag is 1. When the IC\_SR.NACKF flag or TENDF flag is 1, keep the SCL line low after the ninth clock drops. At this point, the communication must be ended by reading I2C\_DRR register, thereby releasing the SCL line.

Figure 30-11 Transmitting Timing Diagram of Slave (2)

### Slave Receiving Mode

If a response processing delay occurs in receiving mode (I2C\_SR.TRA bit=0) and when the received data is full (I2C\_SR.RFULLF flag=1) due to the delay of at least one transmission frame read received data (I2C\_DRR register), etc., the SCL line is automatically maintained low between the 8th SCL and the 9th SCL clock, as shown in the following figure.

Figure 30-12 Slave Receiving Timing Diagram

### Fast ACK/NACK

In SMBUS communication, the data packet error code (PEC) of SMBUS is calculated or the received data is checked using the built-in CRC operator. During a PEC code check, transmits an ACK or NACK based on matching in the last byte. This requires the SCL to be kept low at the falling edge of the eighth clock of the last byte of the received SCL. This satisfies the software processing time. The software writes I2C\_CR1.ACK bit to remove SCL low level according to the calculation results. Fast ACK/NACK is controlled through I2C\_CR3.FACKEN bit, action sequence is shown in the following figure.

Figure 30-13 Fast ACK/NACK Timing Diagram

## 30.3.3 Address Matching

As a slave, two kinds of addresses other than broadcast address and master notification address can be set, and 7-bit address or 10-bit address format can be set for slave address.

### 30.3.3.1 Slave Address Matching

The I2C bus can set two kinds of slave addresses, and has corresponding slave address detection functions. When SLADDR1EN and SLADDR0EN are "1", the subordinate addresses set by I2C\_SLR1 and I2C\_SLR0 register can be detected.

If the set slave address matching are consistent, the corresponding SLADDR1F and SLADDR0F are set to 1 at the rising edge of the 9th clock of the SCL clock, and then the I2C\_SR.RFULLF flag or the I2C\_SR.EMPTIF flag is set to 1 according to the subsequent RW# bit. As a result, either receiving full interrupt or sending empty interrupt can be generated, and can determine which slave address is specified by confirming the I2C\_SR.SLADDR1F, SLADDR0F flags.

The timings of I2C\_SR.SLADDR1F and SLADDR0F flags changing to 1 are shown in the figure below.

The operation after the broadcast address matches is the same as the ordinary slave receiving operation.

### Figure 30-16 Broadcast Address Matching Timing Diagram

### 30.3.3.3 SMBus Master Address Matching

This product has the master address detection function when SMBus runs. If the I2C\_CR1.SMBHOSTEN bit is set to 1 when the I2C\_CR1.SMBUS bit is 1, the master address (0b0001000) can be detected in slave receive mode (I2C\_SR.MSL bit TRA is 0b00).

If the SMBUS master address is detected, the I2C\_SR.SMBHOSTF flag is set to 1 at the rising edge of the 9th clock of SCL clock.

Even if the bit following the SMBUS master address (0b0001000) is the Rd bit (RW# bit receives 1), the SMBUS master address can be detected. The running of SMBUS master address detection is the same as that of normal slave mode.

### Figure 30-17 SMBus Master Address Matching Timing Diagram

#### 30.3.3.4 SMBus Alarm Response Address Matching

This product has the function of alarm response address detection when SMBus is running. If the I2C\_CR1.SMBARLERTEN bit is set to 1 when the I2C\_CR1.SMBUS bit is 1, the SMBUS alarm response address (0b0001100) can be detected in slave receive mode (I2C\_SR.MSL bit TRA is 0b00).

If the SMBUS alarm response address is detected, the I2C\_SR.SMBALRTF flag is set to 1 at the rising edge of the 9th clock of the SCL clock.

The operation of SMBUS alarm response address detection is the same as that of normal slave mode.

Figure 30-18 SMBus Alarm Response Address Matching Timing Diagram

### 30.3.3.5 SMBus Default Address Matching

This product has the default address detection function when SMBus runs. If the I2C\_CR1.SMBDEFAULTEN bit is set to 1 when the I2C\_CR1.SMBUS bit is 1, the SMBUS default address (0b1100001) can be detected in slave receive mode (I2C\_SR.MSL bit TRA is 0b00).

If the SMBUS default address is detected, the I2C\_SR.SMBDEFAULTF flag is set to 1 on the rising edge of the 9th clock of SCL clock.

The SMBUS default address detection runs the same as the normal slave mode.

Figure 30-19 SMBus Default Address Timing Diagram

## 30.3.4 SMBus Action

This I2C interface can perform communication based on SMBus (Ver.2.0). When performing SMBus communication, I2C\_CR1.SMBUS bit must be set to 1. The transmission speed must be set within the SMBus specification range of 10kbps to 100kbps by setting the I2C\_CCR register.

### 30.3.4.1 SMBus Timeout Measurement

#### SCL Level Timeout Measurement

When working in slave mode, after the address match is consistent, it is detected that the low level or high level of the SCL line is fixed for more than a certain time, and the abnormal state of the bus is detected.

When working in the master mode, after the start condition is generated, it is detected that the low level or high level of SCL is fixed for more than a certain time, and the abnormal state of the bus is detected.

The timeout detection function monitors the state of the SCL line, and counts the time of high level or low level through the internal counter. If the SCL line changes (rising/falling), the internal counter is reset, otherwise it continues to count. If the internal counter counts up to the TOUTHIGH/TOUTLOW set value while the SCL line does not change, a timeout is detected and an abnormal state of the bus is notified.

For the counting of the internal counter, it can select whether to count at the low level or high level of the SCL line by setting the HTMOUT and LTMOUT bits, or to count at both low and high levels. If both the HTMOUT and LTMOUT bits are set to 0, no internal counting will be performed.

### Timeout Measurement of Slave

The slave device of SMBus communication needs to measure the interval shown below (timeout interval:  $T_{\text{LOW:SEXT}}$ ):

- Interval from start condition to stop condition

When timeout is measured by the slave device, use the start condition to detect interrupt and stop condition to detect interrupt, and use the chip timer to measure the time from detection to start condition to detection to stop condition. This timeout measurement time must be within the SMBus specification clock low level accumulation time [slave device]  $T_{\text{LOW:SEXT}}$ : 25ms (max).

If the timer measures longer than the timeout of the SMBus specification clock low level detection  $T_{\text{TIMEOUT}}$ : 25ms (min), the slave needs to release the bus.

### Timeout Measurement of Master

The main control device of SMBus communication needs to measure the interval shown below (timeout interval:  $T_{\text{LOW:MEXT}}$ ):

- Interval from start condition to answer bit
- Interval from answer to next answer
- Interval from answer bit to stop condition

When the master performs timeout measurement, use the start condition to detect interrupt, stop condition to detect interrupt, send end interrupt or receive data full interrupt, and use the chip timer to measure the time between intervals. The timeout time must be within the accumulated time [master]  $T_{\text{LOW:MEXT}}$ : 10ms (max) of the clock low level in the SMBus specification, and the cumulative result of all  $T_{\text{LOW:MEXT}}$  from the start condition to the stop condition must be within  $T_{\text{LOW:SEXT}}$ : 25ms (max).

If the time measured by the timer exceeds the cumulative time of the clock low level in the SMBus specification [master device]  $T_{\text{LOW:MEXT}}$ : 10ms (max), or the cumulative result of each measurement time exceeds the timeout of the clock low level detection in the SMBus specification  $T_{\text{TIMEOUT}}$ : 25ms (min), the master needs to terminate the processing. When sending a master, it must immediately abort the transmitting (write I2C\_DTR register). Abort the master transaction by transmitting a stop condition.

#### 30.3.4.2 Packet Error Code (PEC)

In communication, use the CPU to calculate the CRC, transmits the packet error code (PEC) of the SMBus, or checks the received data.

#### 30.3.5 Reset

It has the function of resetting the communication module. There are two types of reset, one is communication reset: all registers inside I2C (except I2C\_FSTR[3:0]) and internal state reset; the other is internal state reset: I2C\_SR (including BUSY bit), internal shift register and internal state machine are reset.

After reset, the I2C\_CR1.SWRST bit must be set to 0.

Because any kind of reset will remove the output state of the SCL pin /SDA pin and change it to a high-impedance state, it can also be used to remove the unexpected shutdown state of the bus.

The reset in the slave mode causes disparity with the master device, so try to avoid using it.

**Notice**

During reset (I2C\_CR1.PE bit and I2C\_CR1.SWRST bit are 0b01), the bus status such as the start condition cannot be monitored.

### 30.3.6 Programmable Digital Filtering

The status of SCL pin and SDA pin is taken internally via analog filter circuit and digital filter. A block diagram of the digital filter circuit is shown below.

Figure 30-20 Digital Filtering Circuit Block Diagram

The internal digital filter circuit is composed of a four-segment series-connected trigger circuit and matching detection circuit.

The number of active segments of the digital filter is selected through the I2C\_FLTR.DNF bit. According to the selected active segment number, the noise elimination capability is 1- 4 I2C periods.

The input signal of the SCL pin (or the input signal of the SDA pin) is sampled on the falling edge of the I2C internal clock. If the output of the trigger circuit with the number of active segments set by the I2C\_FLTR.DNF bit all matches, the level is used as the internal signal to transmit, otherwise it keeps the original value.

### 30.3.7 Interrupt and Event

I2C has four interrupts and event outputs for triggering the activation of other peripheral circuits for user selection. Including: the occurrence of communication errors (arbitration failure detection, NACK detection, timeout detection, start condition detection, stop condition detection), end of receiving, transmitting data empty, end of transmitting.

The interrupt list is as follows.

Table 30-2 Interrupt List

| Name    | Interrupt Source                        | Interrupt Flag | Interrupt Condition     |
|---------|-----------------------------------------|----------------|-------------------------|
| I2C_EEI | Communication Error/Communication Event | ARLOF          | ARLOF=1&ARLOIE=1        |
|         |                                         | SLADDR0F       | SLADDR0F=1&SLADDR0IE=1  |
|         |                                         | SLADDR1F       | SLADDR1F=1&SLADDR1IE=1  |
|         |                                         | SMBALRTF       | SMBALRTF=1&SMBALRTIE=1  |
|         |                                         | SMBHOSTF       | SMBHOSTF=1&SMBHOSTFIE=1 |

| Name    | Interrupt Source                        | Interrupt Flag | Interrupt Condition          |
|---------|-----------------------------------------|----------------|------------------------------|
| I2C_EEI | Communication Error/Communication Event | SMBDEFAULTF    | SMBDEFAULTF=1&SMBDEFAULTIE=1 |
|         |                                         | GENCALLF       | GENCALLF=1&GENCALLIE=1       |
|         |                                         | NACKF          | NACKF=1&NACKIE=1             |
|         |                                         | TMOUTF         | TMOUTF=1&TMOUTIE=1           |
|         |                                         | STARTF         | STARTF=1&STARTIE=1           |
|         |                                         | STOPF          | STOPF=1&STOPIE=1             |
| I2C_RXI | Receive Data Full                       | RFULLF         | RFULLF=1&RFULLIE=1&-FEN      |
|         | Receive FIFO Data is not Empty          | RFREQF         | RFREQF=1&RFREQIE=1&FEN       |
| I2C_TXI | Transmit Data empty                     | EMPTYF         | EMPTYF=1&EMPTYIE=1           |
| I2C_TEI | End of Transmit                         | TENDF          | TENDF=1&TENDIE=1             |

The following table shows the output of the event signal.

Table 30-3 Event Signal Output List

| Name    | Event Source                            | Event Conditions |
|---------|-----------------------------------------|------------------|
| I2C_EEI | Communication Error/Communication Event | ARLOF=1          |
|         |                                         | SLADDR0F=1       |
|         |                                         | SLADDR1F=1       |
|         |                                         | SMBALRTF=1       |
|         |                                         | SMBHOSTF=1       |
|         |                                         | SMBDEFAULTF=1    |
|         |                                         | GENCALLF=1       |
|         |                                         | NACKF=1          |
|         |                                         | TMOUTF=1         |
|         |                                         | STARTF=1         |
|         |                                         | STOPF=1          |
| I2C_RXI | Receive Data Full                       | RFULLF=1         |
| I2C_TXI | Transmit Data Empty                     | EMPTYF=1         |
| I2C_TEI | End of Transmit                         | TENDF=1          |

## 30.4 Operation Example

### 30.4.1 I2C Initialization Process

When start transmitting or receiving data, it must follow the steps below to initialize:

**Step1.** I2C\_CR1.PE bit is set to 0;

**Step2.** Set I2C\_CR1.SWRST to 1, communication reset;

- Step3.** I2C\_CR1.PE bit set to 1, internal state reset;
- Step4.** Set slave address format and address;
- Step5.** Set baud rate;
- Step6.** Set control register function and interrupt as needed;
- Step7.** I2C\_CR1.SWRST bit is set to 0 to cancel internal state reset;
- Step8.** The initialization ends. Can transmit and receive data.

## 30.5 Register Description

### 30.5.1 Register List

- I2C1 base address: 0x4004E000
- I2C2 base address: 0x4004E400
- I2C3 base address: 0x4008E800
- I2C4 base address: 0x4008EC00
- I2C5 base address: 0x4008F000
- I2C6 base address: 0x4008F400

Table 30-4 Inter-Integrated Circuit (I2C) Register Offset

| Offset | Register    | Description                            | Width |
|--------|-------------|----------------------------------------|-------|
| 0x00   | I2C_CR1     | I2C Control Register 1                 | 32    |
| 0x04   | I2C_CR2     | I2C Control Register 2                 | 32    |
| 0x08   | I2C_CR3     | I2C Control Register 3                 | 32    |
| 0x0C   | I2C_CR4     | I2C Control Register 4                 | 32    |
| 0x10   | I2C_SLR0    | I2C Slave Address Register 0           | 32    |
| 0x14   | I2C_SLR1    | I2C Slave Address Register 1           | 32    |
| 0x18   | I2C_SLTR    | I2C SCL Level Timeout Control Register | 32    |
| 0x1C   | I2C_SR      | I2C Status Register                    | 32    |
| 0x20   | I2C_CLR     | I2C Status Clear Register              | 32    |
| 0x24   | I2C_DTR     | I2C Data Transmitting Register         | 8     |
| 0x28   | I2C_DRR     | I2C Data Receiving Register            | 8     |
| 0x2C   | I2C_CCR     | I2C Clock Control Register             | 32    |
| 0x30   | I2C_FLTR    | I2C Filter Control Register            | 32    |
| 0x34   | I2C_FSTR    | I2C FIFO Status Register               | 32    |
| 0x38   | I2C_SLVADRR | I2C Slave Address Receive Register     | 32    |

## 30.5.2 I2C Control Register 1 (I2C\_CR1)

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |       |          |    |    |    |    |   |   |   |   |   |   |   |   |   |   |  |     |      |       |         |      |          |           |              |           |       |    |    |    |    |    |    |    |

### 30.5.11 I2C Data Transmitting Register (I2C\_DTR)

| Offset | Bit Position |   |   |   |   |   |   |   |
|--------|--------------|---|---|---|---|---|---|---|
| 0x24   | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reset  | 0xFF         |   |   |   |   |   |   |   |
| Name   | DT           |   |   |   |   |   |   |   |
| Access | RW           |   |   |   |   |   |   |   |

| Bit | Name | Function      | Description                                                                                                                                                                                           | Access |
|-----|------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 7:0 | DT   | Transmit data | If the internal shift register is empty, the data written to the I2C_DTR register will be transferred to the internal shift register. In transmit mode, the data transmission to the SDA line begins. | RW     |

The internal shift register and the I2C\_DTR register form a double-buffered structure. During the data transmission of the internal shift register, if data is written in advance to the I2C\_DTR register, continuous data transmission can be achieved.

The I2C\_DTR register is readable and writable. Write I2C\_DTR register only once when the transmit data is empty interrupt request occurs.

When the I2C operates in FIFO mode, accessing the I2C\_DTR register address allows direct access to the transmit FIFO. If the current EMPTYF flag is enabled, a write operation to the I2C\_DTR register address writes the current bus data into the transmit FIFO. When the transmit FIFO is enable and the I2C is enabled to transmit, data from the transmit FIFO is transferred to the internal shift register, and data transmission to the SDA line begins.

The selection of the transmit data source is determined by the FEN bit in the FIFO Status Register (I2C\_FSTR) in I2C :

- When FEN is 1, the path from the external data bus to the FIFO and from the FIFO to the internal shift register is selected.
- When FEN is 0, the path from the external data bus to the I2C\_DTR register and from the I2C\_DTR register to the internal shift register is selected.

By default, the non-FIFO mode is selected.

### 30.5.12 I2C Data Receiving Register (I2C\_DRR)

| Offset | Bit Position |   |   |   |   |   |   |   |
|--------|--------------|---|---|---|---|---|---|---|
| 0x28   | 7            | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reset  | 0x00         |   |   |   |   |   |   |   |
| Name   | DR           |   |   |   |   |   |   |   |
| Access | RO           |   |   |   |   |   |   |   |

| Bit | Name | Function     | Description                                                                                                                                                                | Access |
|-----|------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| 7:0 | DR   | Receive Data | If a frame of data is received, the received data can be transferred from the internal shift register to the I2C_DRR register, and then into the next data receiving state | RO     |

The internal shift register and the I2C\_DRR register form a double-buffered structure. During data reception in the internal shift register, if the data in the I2C\_DRR register is read, continuous data reception can be achieved.

Do not write to I2C\_DRR register. Read I2C\_DRR register only once when the receive data full interrupt request occurs.

When the I2C\_SR.RFULLF flag is set to 1 and the data in the I2C\_DRR register is not read before the next data is received, the SCL clock will be automatically held low after the 7th or 8th falling edge during data reception (refer to the [slave receive timing diagram](#) and [the fast ACK/NACK timing diagram](#)), until the data in the I2C\_DRR register is read.

When the I2C operates in FIFO mode, accessing the I2C\_DRR register address directly accesses the receive FIFO:

- If one frame of data is received, the received data will be transferred from the internal shift register to the receive FIFO. Once the receive FIFO has received active data, an RFREQ request status signal will be asserted. At this point, a read operation to the I2C\_DRR register address directly accesses the data in the receive FIFO.
- When the I2C\_SR.RFULLF flag is set to 1 (i.e., the receive FIFO has stored 2 bytes of data and FIFO is full), and if the data in the receive FIFO is not read before the next data is received, the SCL clock will be automatically held low after the 7th or 8th falling edge of the received data, until the data in the receive FIFO is read.

The receive data path of the I2C is selected through the FEN bit in the I2C FIFO Status Register (I2C\_FSTR) :

- When FEN is 1, the data path from the internal shift register to the receive FIFO and from the receive FIFO to the data bus is selected.
- When FEN is 0, the data path from the internal shift register to the I2C\_DRR register and from the I2C\_DRR register to the data bus is selected.

By default, the non-FIFO mode is selected.

## 30.5.13 I2C Clock Control Register (I2C\_CCR)

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |    |       |    |        |    |    |    |    |    |    |       |   |   |   |   |   |   |   |   |   |
|--------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|--------|----|----|----|----|----|----|-------|---|---|---|---|---|---|---|---|---|
| 0x2C   | 31           | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18    | 17 | 16     | 15 | 14 | 13 | 12 | 11 | 10 | 9     | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 15:8  | SHIGHW   | Set SCL high level width bit                 | Setting the high level width of SCL clock                                                                                                                                                                                                                                                                                                                                                                                                                                                   | RW     |
| 7:0   | SLOWW    | Set SCL low level width bit                  | Setting the low level width of SCL clock                                                                                                                                                                                                                                                                                                                                                                                                                                                    | RW     |

The baud rate is calculated as follows:

| I2C_FLTR.DNFE<br>N | I2C_CCR.CKDIV | Baud rate                                                                             |
|--------------------|---------------|---------------------------------------------------------------------------------------|
| 0b0                | 0b000         | $B = \frac{1}{\frac{(SHIGHW + 3) + (SLOWW + 3)}{\phi_{I2C}} + t_R + t_F}$             |
| 0b1                | 0b000         | $B = \frac{1}{\frac{(SHIGHW + 3 + DNF) + (SLOWW + 3 + DNF)}{\phi_{I2C}} + t_R + t_F}$ |
| 0b0                | Non-0         | $B = \frac{1}{\frac{(SHIGHW + 2) + (SLOWW + 2)}{\phi_{I2C}} + t_R + t_F}$             |
| 0b1                | Non-0         | $B = \frac{1}{\frac{(SHIGHW + 2 + DNF) + (SLOWW + 2 + DNF)}{\phi_{I2C}} + t_R + t_F}$ |

Where:

- B: Baud rate, unit: Mbps
- $\Phi I2C$ : I2C reference clock frequency, unit: MHz
- DNF: Digital filter capability, set by the I2C\_FLTR.DNF register
- $t_R$ : Rise time of the SCL line, unit: ns
- $t_F$ : Fall time of the SCL line, unit: ns

#### Note

- In master mode, SHIGHW is used to set the high level width of the SCL clock. The setting has no effect in slave mode.
- In master mode, SLOWW is used to set the low level width of the SCL clock. In slave mode, the set value must be greater than the data setup time ( $t_{SU,DAT}$ ), which is 250ns for standard mode and 100ns for fast mode.
- The rise time ( $t_R$ ) and fall time ( $t_F$ ) of the SCL line depend on the total bus capacitance ( $C_b$ ) and pull-up resistance ( $R_p$ ). For detailed information, refer to the I2C bus specification.

## 31 Serial Peripheral Interface (SPI)

### 31.1 Introduction

This product is equipped with 6-channel serial peripheral interface SPI, supports high-speed full-duplex serial synchronous transmission, and facilitates data exchange with peripheral devices. Users can set the range of 3/4-wire, master/slave and baud rate as as required.

### 31.2 Features

Table 31-1 SPI Main Features

| Essentials                          | Description                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Note**

When the communication auto-suspend feature is used in master receive mode, overload errors will not occur because the communication clock stops. Refer to "[Overload Error](#)" for more information.

## 31.3 Functional Description

### 31.3.1 System Block Diagram

Figure 31-1 SPI System Block Diagram

Table 31-2 Pin Description

| Pin Name | Port direction | Function                      |
|----------|----------------|-------------------------------|
| SCK      | Input/Output   | Communication clock pin       |
| MOSI     | Input/Output   | Master data transmission pin  |
| MISO     | Input/Output   | Slave data transmission pin   |
| SS0      | Input/Output   | Slave select input/output pin |
| SS1      | Output         | Slave select output pin       |
| SS2      | Output         | Slave select output pin       |

| Pin Name | Port direction | Function                |
|----------|----------------|-------------------------|
| SS3      | Output         | Slave select output pin |

### 31.3.2 SPI Action System Description

#### 31.3.2.1 Pin Status in Master Mode

When SPI works in master mode, the status of each pin is shown below.

Table 31-3 SPI Pin Status Description in Master Mode

| Mode                                       |                               | Pin Name           | Pin Status                      |
|--------------------------------------------|-------------------------------|--------------------|---------------------------------|
| SPI Action (SPIMDS=0)                      | Master Mode (MSTR=1, MODFE=0) | SCK                | Output                          |
|                                            |                               | SS0-SS3            | Output                          |
|                                            |                               | MOSI               | Output                          |
|                                            |                               | MISO               | Input                           |
| Clock Synchronization Operation (SPIMDS=1) | Master Mode (MSTR=1)          | SCK                | Output                          |
|                                            |                               | SS0-SS3 (not used) | Hi-Z (available as general I/O) |
|                                            |                               | MOSI               | Output                          |
|                                            |                               | MISO               | Input                           |

#### Note

Please set the pin input type to CMOS input and the output type to high drive mode. For related settings, please refer to "General-Purpose IO (GPIO) " "Register-General Control Register (PCRxy) ".

#### 31.3.2.2 Pin Status in Slave Mode

When SPI works in slave mode, the status of each pin is shown below.

Table 31-4 SPI Pin Status Description in Slave Mode

| Mode                                       |                              | Pin Name            | Pin Status                      |
|--------------------------------------------|------------------------------|---------------------|---------------------------------|
| SPI Action (SPIMDS=0)                      | Slave Mode (MSTR=0, MODFE=0) | SCK                 | Input                           |
|                                            |                              | SS0                 | Input                           |
|                                            |                              | SS1- SS3 (not used) | Hi-Z (available as general I/O) |
|                                            |                              | MOSI                | Input                           |
|                                            |                              | MISO                | Output/Hi-Z                     |
| Clock Synchronization Operation (SPIMDS=1) | Slave Mode (MSTR=0)          | SCK                 | Input                           |
|                                            |                              | SS0-SS3 (not used)  | Hi-Z (available as general I/O) |
|                                            |                              | MOSI                | Input                           |
|                                            |                              | MISO                | Output                          |

**Note**

Please set the pin input type to CMOS input and the output type to high drive mode. For related settings, please refer to "General-Purpose IO (GPIO) " "Register-General Control Register (PCRxy) ".

### 31.3.2.3 SPI System Connection Examples

#### Master Mode

In the master-multi-slave mode SPI system architecture, the master drives SCK, MOSI, and SS0-SS3. In SPI slave equipment 0-3, the slave equipment drives the MISO when the SS input of a slave computer is a active level.

Figure 31-2 Master Mode Structure

#### Clock Synchronization Operation

In the SPI system structure used for clock synchronous operation, the master device drives SCK and MOSI, and the slave device drives MISO. SS pins are not used.

Figure 31-3 Three-wire Clock Synchronization Operation

### 31.3.3 Data Communication Description

#### 31.3.3.1 Baud Rate

In master mode, SPI clock is provided by internal baud rate generator. In slave mode, the clock is input to the SCK pin.

Baud rate depends on SPI\_CFG2.MBR bit setting. The calculation method is shown in the following formula:

$$\text{Baud Rate} = \frac{f_{\text{PCLK1}}}{2^{N+1} \times (M+1)}$$

Where:

- N: SPI\_CFG2.MBR bit setting value, the range is from 0-3;
- M: SPI\_CFG1.CLKDIV bit setting value, the range is from 0-15.

Table 31-5 Bit Speed of Some Set Values

| MBR Bit Setting Value (N) | CLKDIV Bit Setting Value (M) | Frequency Dividing Ratio | Baud Rate  |             |             |             |
|---------------------------|------------------------------|--------------------------|------------|-------------|-------------|-------------|
|                           |                              |                          | PCLK1=5MHz | PCLK1=10MHz | PCLK1=20MHz | PCLK1=40MHz |
| 0                         | 0                            | 2                        | 2.50Mbps   | 5.00Mbps    | 10.0Mbps    | 20.0Mbps    |
| 0                         | 1                            | 4                        | 1.25Mbps   | 2.50Mbps    | 5.00Mbps    | 10.0Mbps    |
| 0                         | 3                            | 8                        | 625kbps    | 1.25Mbps    | 2.50Mbps    | 5.00Mbps    |
| 0                         | 7                            | 16                       | 313kbps    | 625kbps     | 1.25Mbps    | 2.50Mbps    |
| 0                         | 15                           | 32                       | 156kbps    | 313kbps     | 625kbps     | 1.25Mbps    |
| 1                         | 15                           | 64                       | 78kbps     | 156kbps     | 313kbps     | 625kbps     |
| 2                         | 15                           | 128                      | 39kbps     | 78kbps      | 156kbps     | 313kbps     |
| 3                         | 15                           | 256                      | 20kbps     | 39kbps      | 78kbps      | 156kbps     |

#### 31.3.3.2 Data Format

The data format of SPI depends on the setting value of SPI\_CFG2 register and SPI\_CR.PAE bit setting value. SPI treats the data of a certain length starting from the LSB bit in the data register SPI\_DR (the data length is set by the SPI\_CFG2.DSIZE) as the transfer object, regardless of the MSB/LSB shift order.

SPI\_CFG2.DSIZE determines the bit width of the data. The bit width range is 4-32 bits. SPI\_CR.PAE determines the last bit of the data. When PAE is 1, the last bit is used as the parity bit. When it is 0, it is the lowest bit of the data itself.

Figure 31-4 Data Format

When sending SPI data, the transmitted data first enters the transmit buffer (TX\_BUFF), and then the data in the TX\_BUFF is copied to the SHIFTER register. The SHIFTER sequentially outputs the data. During SPI data reception, data is sequentially shifted in from the SHIFTER. Once the shifting is complete, the data in the SHIFTER is copied to the receive buffer (RX\_BUFF).

During data transmission, there are four situations according to the settings of the shift order control bit SPI\_CFG2.LSBF and the parity control bit SPI\_CR.PAE:

- **MSB Transmitted First, Parity Invalid**

During transmitting, data D31-D0 is copied sequentially from TX\_BUFF to the SHIFTER and shifted out from the highest bit of the SHIFTER in the sequence of D31-D0.

During receiving, data D31-D0 is shifted in from the least significant bit of the SHIFTER and copied to RX\_BUFF after all bits have been received.

Figure 31-5 MSB Transmitted First, Parity Invalid

- **LSB Transmitted First, Parity Invalid**

During transmitting, D31-D0 is copied from TX\_BUFF to SHIFTER in the sequence of D0-D31, and shifted out from the highest bit of the SHIFTER in the sequence of D0-D31.

During receiving, data D0-D31 is moved in from the lowest bit of SHIFTER, and then copied from SHIFTER to RX\_BUFF in the order D31-D0 after all data is moved in.

Figure 31-6 LSB Transmitted First, Parity Invalid

### ● MSB Transmitted First, Parity Valid

During transmitting, the value of parity bit P is calculated according to the value of D31-D1, then P is replaced by D0, copied to SHIFTER according to the order of D31-D1, P, and shifted out from the highest bit of the SHIFTER in the sequence of D31-P.

During receiving, the data D31-P moves in from the lowest bit of SHIFTER, and parity is performed when the data is copied to SHIFTER. Finally, copy the data to RX\_BUFF.

Figure 31-7 MSB Transmitted First, Parity Valid

### ● LSB Transmitted First, Parity Valid

During transmitting, the value of parity bit P is calculated according to the value of D30-D0, and then P is used instead of D31, which is copied from TX\_BUFF to SHIFTER in the sequence of D0-P and shifted out from the highest bit of the SHIFTER in the sequence of D0-P.

During receiving, the data D0-P moves in from the lowest bit of SHIFTER, and parity is performed when the data is copied to SHIFTER. The data D0-P is rearranged at the time of replication and copied to RX\_BUFF in the sequence of P-D0.

Figure 31-8 LSB Transmitted First, Parity Valid

### 31.3.3.3 Transfer Format

#### CPHA=0

When the SPI\_CFG2.CPHA bit is 0, SPI samples data on the odd edges of SCK and updates data on the even edges. The figure below is the SPI transmission timing diagram when CPHA=0. When the input level of the SSi signal becomes a active level, MOSI/MISO starts to update the transmission data. After the SSi signal becomes active for the first time on the edge of the first SCK signal, the data is sampled once per SCK period. MOSI/MISO signals are updated at 1/2 SCK periods after each sampling. The set value of CPOL bit does not affect the running time of SCK signal, but only affects the polarity of signal.

Figure 31-9 Data Transmission Format Diagram (CPHA=0)

In the above figure, t1 represents the interval from the SS signal being active to the SCK oscillation (SCK delay time, which can be controlled by setting SPI\_CFG1.MSSI and SPI\_CFG2.MSSIE), t2 represents the interval from the SCK oscillation stopping to the SS signal becoming inactive (SS inactive delay time, which can be controlled by setting SPI\_CFG1.MSSDL and SPI\_CFG2.MSSDLE), and t3 represents the minimum waiting time from the end of serial transmission to the start of the next transmission (the next access delay, which can be controlled by setting SPI\_CFG1.MIDI and SPI\_CFG2.MIDIE). t1, t2 and t3 are controlled by the master device on the SPI system. For details, see "[Master Action in SPI Operation Mode](#)".

#### CPHA=1

When SPI\_CFG2.CPHA bit is "1", SPI updates the data at the odd edge of SCK and samples the data at the even edge. The figure below is the SPI transmission timing diagram when CPHA=1. MOSI/MISO starts

to transmit data updates at the edge of the first SCK signal after the SSI signal becomes active. After this, data is updated every SCK period. Data is sampled at 1/2 SCK periods after each update. The set value of the SPI\_CFG2.CPOL bit does not affect the timing of the operation of the SCK signal but only affects the polarity of the signal.

Figure 31-10 Data Transmission Format Diagram (CPHA=1)

t1, t2, t3 are the same as when the CPHA bit is 0.

#### 31.3.3.4 Communication Method

This SPI has two communication modes: Full-duplex synchronous serial communication and transmit-only communication, which can be selected through the SPI\_CR.TXMDS bit.

#### Full-duplex Synchronous serial Communication Mode

When the SPI\_CR.TXMDS bit is set to 0, the SPI operates in full-duplex synchronous serial communication mode. As shown in the figure below, the SPI\_CFG1.FTHLV bit is 0b00, the SPI\_CFG2.CPHA bit is 1 and the SPI\_CFG2.CPOL bit is 0, and the SPI performs 8-bit serial transmission.

Figure 31-11 Full-duplex Synchronous Serial Communication

**Note**

1. When the serial transmission ends, if the receive buffer is empty, SPI will copy the received data from the SHIFTER register to the receive buffer, the receive buffer full flag RDFF is set to 1, and a receive data full interrupt request SPRI is generated.
2. When the serial transmission ends, if the receive buffer still holds the data received last time and has not been read by the system, the SPI will set the data overload flag OVRERF to 1, the data reception will be inactive, and the data in the receive SHIFTER register will be discarded.

**Transmit-Only Communication Mode**

When the SPI\_CR.TXMDS bit is set to 1, the SPI operates in transmit-only communication mode. As shown in the figure below, the SPI\_CFG1.FTHLV bit is 0b00, the SPI\_CFG2.CPHA bit is 1 and the SPI\_CFG2.CPOL bit is 0, and the SPI performs 8-bit serial transmission.

**Figure 31-12 Transmit-only Communication****Note**

1. Before setting up the transmit-only communication mode, make sure that there is no unread data in the receive buffer (RDFF=0) and no data overload error (OVRERF=0).
2. In the transmit-only communication mode, when the serial transmission ends, no data will be received even if the receive buffer is empty, and RDFF will always remain 0.
3. In the transmit-only communication mode, since the receive buffer is always empty, no data overload error will occur and the OVRERF flag will always remain 0.

**31.3.3.5 Communication Interval Time****Communication Interval Time Under Normal Communication Setting**

When the SPI\_CFG1.CTMDS bit is set to 0, the SPI uses normal communication setting. The interval time between two consecutive communications can be set by SPI\_CFG1.MIDI and SPI\_CFG2.MIDIE. The minimum interval time is  $1 \times \text{SCK} + 2 \times \text{PCLK1}$ . As shown in the figure below, the SPI\_CFG2.CPHA bit is 1 and the SPI\_CFG2.CPOL bit is 0, and the SPI performs serial transmission.

Figure 31-13 Normal Communication

In the above figure,  $t_1$  represents the time interval from the active SS signal to the first edge of SCK (SCK delay time, which can be controlled by setting SPI\_CFG1.MSSI and SPI\_CFG2.MSSIE),  $t_2$  represents the time interval from the last edge of SCK to the inactive SS signal (SS inactive delay time, which can be controlled by setting SPI\_CFG1.MSSDL and SPI\_CFG2.MSSDLE), and  $t_3$  represents the minimum waiting time from the end of this transmission to the beginning of the next transmission (the next access data delay, which can be controlled by setting SPI\_CFG1.MIDI and SPI\_CFG2.MIDIE).

**Note**

When the communication rate is 2 divided by PCLK1 (SPI\_CFG2.MBR=0b00 and SPI\_CFG2.CLKDIV=0b0000), please configure  $t_3$  to  $2 \times \text{SCK} + 2 \times \text{PCLK1}$  or above, that is, SPI\_CFG2.MIDIE=1 and SPI\_CFG1.MIDI=0x1-0x7.

### Communication Interval Time Under Continuous Communication Setting

When the SPI\_CFG1.CTMDS bit is set to 1, the SPI uses the continuous communication setting. Completely continuous and uninterrupted data communication can be achieved. As shown in the figure below, the SPI\_CFG2.CPHA bit is 1 and the SPI\_CFG2.CPOL bit is 0, and the SPI performs serial transmission.

Figure 31-14 Continuous Communication

In the above figure,  $t_1$  represents the time interval from the activity of the SS signal to the first edge of SCK (SCK delay time, which can be controlled by setting SPI\_CFG1.MSSI and SPI\_CFG2.MSSIE), and  $t_4$  represents the time interval between each transmission, which can be controlled by setting SPI\_CFG1.MSSI and SPI\_CFG2.MSSIE. The relationship between  $t_1$  and  $t_4$  is defined as  $t_4 = t_1 - 1 \times \text{SCK}$ .

**Note**

- In continuous communication mode, if the master has no new data written into the transmit buffer, it will enter a pause state, SCK stops outputting, and the SS signal remains active, waiting for new transmit data to be written into the transmit buffer before continuing to transmit the next frame of data.
- In continuous communication mode, if the slave has no new data written into the transmit buffer, an underload error will occur and SPI\_SR.MODFERF and SPI\_SR.UDRERF will be set to 1. For detailed description, see "[Underload Error](#)".
- For continuous communication in clock synchronization mode, if the transmission format with CPHA=0 is used, ensure that the data is written before CPHA is set to 0.
- When using the transmission format of CPHA=0, the slave needs to write new data to the transmit buffer before the previous frame of data is sent. Otherwise, no matter whether the master starts the communication of the next frame of data, the slave will have an underload error.
- In continuous communication mode, the time interval between the last SCK of the previous frame of data and the first SCK of the next frame of data can also be adjusted through MSS1.

### 31.3.4 Operating Instructions

#### 31.3.4.1 Operational Mode Overview

This SPI supports 4-wire SPI mode and 3-wire clock synchronization mode. Serial communication can be performed as a master or slave in each operating mode. Set the SPI\_CR.MSTR and SPI\_CR.SPIMDS bits to set the SPI mode. The relationship between the SPI mode and the SPI\_CR register setting and the overview of each mode are shown in the following table.

Table 31-6 SPI Mode and Register Setting Relationship

| Mode                        | Master (SPI Operation)       | Slave (SPI Operation) | Master (Clock Synchronous Operation) | Slave (Clock Synchronous Operation) |
|-----------------------------|------------------------------|-----------------------|--------------------------------------|-------------------------------------|
| MSTR bit setting            | 1                            | 0                     | 1                                    | 0                                   |
| SPIMDS bit setting          | 0                            | 0                     | 1                                    | 1                                   |
| SCK signal                  | Output                       | Input                 | Output                               | Input                               |
| MOSI signal                 | Output                       | Input                 | Output                               | Input                               |
| MISO signal                 | Input                        | Output/Hi-Z           | Input                                | Output                              |
| SS0 signal                  | Output                       | Input                 | Hi-Z (not used)                      | Hi-Z (not used)                     |
| SS1-SS3 signal              | Output                       | Hi-Z                  | Hi-Z (not used)                      | Hi-Z (not used)                     |
| SS polarity change function | Yes                          | Yes                   | -                                    | -                                   |
| Maximum transmission rate   | PCLK1/2                      | PCLK1/6               | PCLK1/2                              | PCLK1/6                             |
| Clock source                | Internal baud rate generator | SCK input             | Internal baud rate generator         | SCK input                           |
| Clock polarity              | 2 species                    | 2 species             | 2 species                            | 2 species                           |
| Clock phase                 | 2 species                    | 2 species             | 2 species                            | 2 species <sup>*3</sup>             |
| Start transfer bit          | MSB/LSB                      | MSB/LSB               | MSB/LSB                              | MSB/LSB                             |

| Mode                            | Master (SPI Operation)                                           | Slave (SPI Operation)             | Master (Clock Synchronous Operation)                             | Slave (Clock Synchronous Operation) |
|---------------------------------|------------------------------------------------------------------|-----------------------------------|------------------------------------------------------------------|-------------------------------------|
| Transmission data length        | 4-32 bits                                                        | 4-32 bits                         | 4-32 bits                                                        | 4-32 bits                           |
| SCK delay control               | Yes                                                              | No                                | Yes                                                              | No                                  |
| SS inactive delay control       | Yes                                                              | No                                | Yes                                                              | No                                  |
| Next access delay control       | Yes                                                              | No                                | Yes                                                              | No                                  |
| Transport start method          | Write transmit buffer by transmit buffer empty interrupt request | SS input active or SCK clock edge | Write transmit buffer by transmit buffer empty interrupt request | SCK oscillation                     |
| Mode failure error              | No                                                               | Yes                               | No                                                               | Yes                                 |
| Transmit buffer empty detection | Yes                                                              | Yes                               | Yes                                                              | Yes                                 |
| Receive buffer full detection   | Yes <sup>*1</sup>                                                | Yes <sup>*1</sup>                 | Yes <sup>*1</sup>                                                | Yes <sup>*1</sup>                   |
| Overload error detection        | Yes <sup>*1</sup>                                                | Yes <sup>*1</sup>                 | Yes <sup>*1</sup>                                                | Yes <sup>*1</sup>                   |
| Parity error detection          | Yes <sup>*1 *2</sup>                                             | Yes <sup>*1 *2</sup>              | Yes <sup>*1 *2</sup>                                             | Yes <sup>*1 *2</sup>                |
| Underload error detection       | No                                                               | Yes                               | No                                                               | Yes                                 |

**Note**

1. When the SPI\_CR.TXMDS bit is 1, the receive buffer full detection, overload error detection, and parity error detection are not performed.
2. When the SPI\_CR.PAE bit is 0, parity error detection is not performed.
3. When the SPI\_CFG2.CPHA bit is 0, it is only active in continuous transmission mode. For specific setting steps, please refer to "[Slave Action in Clock Synchronous Operation Mode](#)".

### 31.3.4.2 Master Action in SPI Operation Mode

#### Action Description as Master

When the SPI data transmit buffer (TX\_BUFF) is empty (SPI\_SR.TDEF is 1), write the data of the frame length set by the SPI\_CFG1.FTHLV to the SPI\_DR register, SPI will update the SPI\_DR data to TX\_BUFF. If the SHIFTER register is empty, SPI copies the TX\_BUFF data to the SHIFTER register to start serial transmission.

When transmit data is copied to SHIFTER, SPI will change SHIFTER state to full state; When serial delivery is over, change to empty. The status of SHIFTER cannot be read.

After the SPI has generated the final SCK edge required for the last sampling timing, the current serial transmission concludes. The completion time is independent of the SPI\_CFG2.CPHA bit. When the

receive buffer (RX\_BUFF) is empty, SPI copies the data from SHIFTER to RX\_BUFF after serial delivery, which can be read by the SPI\_DR register.

The final sampling timing depends on the bit length of the transmit data, and the SPI data length of the master mode depends on SPI\_CFG2.DSIZE. The polarity of the SS output pin depends on the set value of SPI\_CFG1 register. For details about the SPI transfer format, see "[Transfer Format](#)".

### Initialization of SPI Master Mode

- Step1.** Set the SPI\_CFG1 register, including the setting of the baud rate, the setting of the number of frames used, the setting of various delay times, etc.;
- Step2.** Set the SPI\_CFG2 register, including SS level setting, data shift sequence setting, various delay allow bit setting, data format and clock polarity phase setting, etc.;
- Step3.** If you need to use interrupt, set the interrupt register of the system;
- Step4.** If you need to use DMA, set the relevant register for DMA;
- Step5.** Set the input/output pin;
- Step6.** Set the SPI\_CR register, including the mode and operation mode settings, self-diagnosis function settings, parity check settings, etc.;
- Step7.** Confirm the setting of SPI\_CR register;
- Step8.** Clear various flag bits;
- Step9.** Set the interrupt permission bit;
- Step10.** Set the SPI\_CR.SPE bit to 1 and the action starts.

### 31.3.4.3 Slave Action in SPI Operation Mode

#### Action Description as Slave

When the SPI\_CFG2.CPHA bit is 0, if SPI detects that the SS0 input signal becomes active, it needs to start to output the signal to MISO to drive the active data. Therefore, when the CPHA bit is 0, the SS0 input signal level is changed from inactive to active as a trigger signal that starts serial transmission.

When the CPHA bit is 1, if SPI detects the original SCK edge when the SS0 input signal is at an active level, it needs to start to drive active data to the MISO output signal. Therefore, when the CPHA bit is 1, the first SCK edge of the SS0 signal in the active state is considered as the trigger signal that starts serial transmission.

If SPI detects the start of serial delivery in the SHIFTER empty state, it changes SHIFTER to full state and cannot transfer data from TX\_BUFF to SHIFTER during serial delivery. If SHIFTER is full before starting serial transfer, SPI keeps SHIFTER full.

If SPI detects the SCK edge of the last sampling sequence, the current serial transmission concludes. The completion time is independent of the SPI\_CFG2.CPHA bit. When RX\_BUFF is empty, SPI copies the data from SHIFTER to RX\_BUFF after serial delivery. The data can be read by accessing SPI\_DR. SPI changes SHIFTER to an empty state after serial delivery, independent of the state of RX\_BUFF.

During serial delivery, a mode fault error occurs if SPI detects that the SS0 input signal is disabled.

The final sampling timing depends on the bit length of the transmit data, and the SPI data length depends on SPI\_CFG2.DSIZE. The polarity of SS0 input signal depends on SPI\_CFG1.SS0PV bit setting. For details about the SPI transfer format, see "[Transfer Format](#)".

**Note**

When the SPI\_CFG2.CPHA bit is 0, the SS0 input signal level is changed from inactive to active as a trigger signal to start serial transmission. Since the SS0 input signal is fixed in a slave mode, SPI will not start serial transmission normally. Therefore, in the structure where the SS0 input signal is fixed to the active state, the CPHA bit must be set to 1 in order to send and receive the SPI in the slave mode normally. If you need to set the CPHA bit to 0, you cannot fix the SS0 input signal.

**Initialization of SPI Slave Mode**

- Step1.** Set the SPI\_CFG1 register, mainly including the setting of the number of frames used;
- Step2.** Set the SPI\_CFG2 register, including transmission rate, data format and clock polarity phase setting;
- Step3.** If you need to use interrupt, set the interrupt register of the system;
- Step4.** If you need to use DMA, set the relevant register for DMA;
- Step5.** Set the input/output pin;
- Step6.** Set the SPI\_CR register, including the mode and operation mode settings, self-diagnosis function settings, parity check settings, etc.;
- Step7.** Confirm the setting of SPI\_CR register;
- Step8.** Clear various flag bits;
- Step9.** Set the interrupt permission bit;
- Step10.** Set the SPI\_CR.SPE bit to 1 and the action starts.

**31.3.4.4 Master Action in Clock Synchronous Operation Mode**

When the SPI\_CR.SPIMDS bit is 1, the SPI is in clock synchronous operation mode. When operating in this mode, SPI only uses the 3 pins SCK, MOSI and MISO for communication, and the SSi pin is released for normal I/O functions.

Although the SSi pins are not used in the clock synchronous operation mode, the internal operation of the module is the same as the SPI mode of operation.

**Action Description as Master**

When the SPI data transmit buffer (TX\_BUFF) is empty (SPI\_SR.TDEF is 1), write the data with the frame length set by the SPI\_CFG1.FTHLV to the SPI\_DR register, SPI will update the SPI\_DR data to TX\_BUFF. If the SHIFTER register is empty, SPI copies the TX\_BUFF data to the SHIFTER register to start serial transmission.

When transmit data is copied to SHIFTER, SPI will change SHIFTER state to full state; When serial delivery is over, change to empty. The status of SHIFTER cannot be read.

After the SPI has generated the final SCK edge required for the last sampling timing, the current serial transmission concludes. The completion time is independent of the SPI\_CFG2.CPHA bit. When the receive buffer (RX\_BUFF) is empty, SPI copies the data from SHIFTER to RX\_BUFF after serial delivery, which can be read by the SPI\_DR register.

The final sampling timing depends on the bit length of the transmit data, and the SPI data length of the master mode depends on SPI\_CFG2.DSIZE. For details about the SPI transfer format, see "[Transfer Format](#)".

**Master Initialization in Clock Synchronous Operation Mode**

- Step1.** Set the SPI\_CFG1 register, including the setting of the baud rate, the setting of the number of frames used, the setting of various delay times, etc.;

- Step2.** Set the SPI\_CFG2 register, including the data shift sequence setting, the setting of the allowable bit of various delays, the setting of the data format and the clock polarity phase, etc.;
- Step3.** If you need to use interrupt, set the interrupt register of the system;
- Step4.** If you need to use DMA, set the relevant register for DMA;
- Step5.** Set the input/output pin;
- Step6.** Set the SPI\_CR register, including the mode and operation mode settings, self-diagnosis function settings, parity check settings, etc.;
- Step7.** Confirm the setting of SPI\_CR register;
- Step8.** Clear various flag bits;
- Step9.** Set the interrupt permission bit;
- Step10.** Set the SPI\_CR.SPE bit to 1 and the action starts.

### 31.3.4.5 Slave Action in Clock Synchronous Operation Mode

#### Action Description as Slave

When the SPI\_CFG2.CPHA bit is 0, the SPI needs to detect that the SS0 input signal becomes a active level as a trigger signal to start serial communication. Since the SS0 pin is not used in the clock synchronous operation mode, the following sequence must be followed for normal communication:

- Step1.** Set up communication and set the SPI\_CR.SPE to 1;
- Step2.** Set SPI\_CFG2.CPHA to 1;
- Step3.** Set SPI\_CFG1.CTMDS to 1;
- Step4.** Write transmit data to SPI\_DR;
- Step5.** Set SPI\_CFG2.CPHA to 0;
- Step6.** Waiting for the master clock to start communicating.

When the CPHA bit is 1, if SPI detects the original SCK edge when the SS0 input signal is at an active level, it needs to start to drive active data to the MISO output signal. Since the SS0 pin is not used in the clock synchronous mode of operation, when the CPHA bit is 1, the first SCK edge is considered as the trigger signal to start the serial transmission.

If SPI detects the start of serial delivery in the SHIFTER empty state, it changes SHIFTER to full state and cannot transfer data from TX\_BUFF to SHIFTER during serial delivery. If SHIFTER is full before starting serial transfer, SPI keeps SHIFTER full.

If SPI detects the SCK edge of the last sampling sequence, the current serial transmission concludes. When RX\_BUFF is empty, SPI copies the data from SHIFTER to RX\_BUFF after serial delivery. The data can be read by accessing SPI\_DR. SPI changes SHIFTER to an empty state after serial delivery, independent of the state of RX\_BUFF.

The final sampling timing depends on the bit length of the transmitted data, and the data length of the SPI in slave mode depends on SPI\_CFG2.DSIZE.

#### Slave Initialization in Clock Synchronous Operation Mode

- Step1.** Set the SPI\_CFG1 register, mainly including the setting of the number of frames used;
- Step2.** Set the SPI\_CFG2 register, including transmission rate, data format and clock polarity phase setting, etc.;
- Step3.** If you need to use interrupt, set the interrupt register of the system;
- Step4.** If you need to use DMA, set the relevant register for DMA;
- Step5.** Set the input/output pin;

- Step6.** Set the SPI\_CR register, including the mode and operation mode settings, self-diagnosis function settings, parity check settings, etc.;
- Step7.** Confirm the setting of SPI\_CR register;
- Step8.** Clear various flag bits;
- Step9.** Set the interrupt permission bit;
- Step10.** Set the SPI\_CR.SPE bit to 1 and the action starts.

#### 31.3.4.6 Processing Flow of Several SPI Actions

##### SPI Data Transmission Process as Master

- Step1.** Wait for the interrupt of the data transmit buffer being empty or confirm that the data transmit buffer is in an empty state by polling;
- Step2.** Writes the transmit data to SPI\_DR register;
- Step3.** Repeat steps 1 and 2 until the final data is transmit;
- Step4.** Reset the allowable bit TXIE of transmit data register empty interrupt, and set the allowable bit IDIE of SPI idle state interrupt to 1;
- Step5.** The hardware generates an SPI idle state interrupt;
- Step6.** Set SPE to 0, stop SPI, and reset IDIE.

##### Data Reception Process

- Step1.** Wait for the full interrupt of the data receive buffer register or confirm by polling that the data receive buffer register is full;
- Step2.** Read data from the receive buffer register by accessing SPI\_DR;
- Step3.** Repeat steps 1 and 2 until the last received data is read;
- Step4.** Clears the RXIE bit for the full interrupt of the data receive buffer register.

##### Communication Error Process

- Step1.** Wait for the communication error interrupt or confirm that the communication error flag bit (MODFERF/OVERRF/UDRERF/PERF) is set to 1 by polling;
- Step2.** Verify SS0 status and troubleshoot mode errors;
- Step3.** Clear SPE and stop SPI;
- Step4.** Identify the types of communication errors by error flag bits and handle them;
- Step5.** Clear the error flag bit;
- Step6.** Start SPI and restart the communication.

#### 31.3.5 Self-diagnosis of Parity

Parity check circuit is composed of parity check bits for transmitting data and error detection part for receiving data. You can use the self-diagnosis function to diagnose the fault of the parity circuit as shown in the following figure.

Figure 31-15 Parity Check Process

### 31.3.6 Error Detection

#### 31.3.6.1 Error Detection Overview

In the normal SPI serial transmission, the system writes the data serially to SPI\_DR register and obtains the data serially received by reading SPI\_DR register. However, due to the status of the transmit/receive buffer and the SPI at the start/end of serial delivery, abnormal delivery may occur in some cases. When an abnormal transfer occurs, SPI detects this transfer as an underload error, an overload error, a parity error, or a mode fault error. The correspondence between abnormal transmission and SPI error detection is shown in the following table.

Table 31-7 Error Detection Correspondence Table

| SN | Occurrence Condition                              | SPI Operation                    | Detect Errors |
|----|---------------------------------------------------|----------------------------------|---------------|
| ①  | Write SPI_DR register in full transmit buffer     | Hold transmit buffer content     | No            |
|    |                                                   | Write data loss                  |               |
| ②  | Read SPI_DR register when receive buffer is empty | Output last serial received data | No            |

| SN | Occurrence Condition                                                                                             | SPI Operation                      | Detect Errors   |
|----|------------------------------------------------------------------------------------------------------------------|------------------------------------|-----------------|
| ③  | In slave mode, serial delivery begins without data being transferred to the SHIFTER register                     | Aborting serial transmission       | Underload Error |
|    |                                                                                                                  | Loss of sending and receiving data |                 |
|    |                                                                                                                  | Stop driving MISO output signal    |                 |
|    |                                                                                                                  | Stop SPI function                  |                 |
| ④  | Slave mode: The active level width of the SS0 pin does not reach the time required for data transmission         | Abort transmission                 | Mode Error      |
|    |                                                                                                                  | Loss of sending and receiving data |                 |
|    |                                                                                                                  | Stop SPI function                  |                 |
| ⑤  | End serial transfer in full receive buffer                                                                       | Hold receive buffer content        | Overload Error  |
|    |                                                                                                                  | Loss of received data              |                 |
| ⑥  | Error parity bits are received in full-duplex synchronous serial communication and the parity function is active | Parity error flag is valid         | Parity Error    |

In case ① described, SPI does not detect errors. To prevent data omissions during data write to SPI\_DR register, data must be written to SPI\_DR register by an empty interrupt of the transmit buffer. Similarly in case ②, SPI does not detect errors. To prevent unrelated data from being read, SPI\_DR data read must be done by a full interrupt request of receive register.

### 31.3.6.2 Underload Error

When the MSTR bit is 0, the SPI operates in the slave state. If the SPE is set to 1, the transmission data is not ready before the SS0 pin receives a active level, and the SPI has an underload error, SPI\_SR.MODFERF and SPI\_SR.UDRERF will be set to 1.

When an underload error is detected, SPI will stop driving signal output, and SPI\_CR.SPE is set to 0.

Monitoring of underload errors can be done by accessing SPI\_SR register directly, or by using SPI error interrupt to read SPI\_SR. If you do not use the error interrupt, use the polling method to monitor for unloaded errors.

When SPI\_SR.MODFERF is 1, the system disables writing 1 to SPE bits. To set SPI\_CR.SPE to 1 to enable the SPI function, the MODFERF flag must be cleared to 0 first.

### 31.3.6.3 Mode Error

When SPI is in master mode, please do not set SPI\_CR.MODFE to 1. In slave mode, when the SSi active level width does not reach the time required for data transmission, a mode fault occurs, SPI\_SR.MODFERF is set to 1, and SPI\_CR.SPE is set to 0. When transmission is required, set SPI\_CR.SPE to 1 after clearing SPI\_SR.MODFERF.

### 31.3.6.4 Overload Error

SPI\_SR.OVRERF flag is set to 1 if serial delivery is ended in full receive buffer. Since SPI does not copy the data of the SHIFTER register to the receive buffer in the case of the OVRERF flag is 1, the receive buffer stores the received data before the error occurs. The OVRERF flag only can be written to 0 after the SPI\_SR register is read when the OVRERF flag is 1.

Figure 31-16 Overload Error Processing

The following describes the operation content of the flags in the sequence shown in ①-⑥ in the figure:

① When the receive buffer is empty, the serial transmission ends, the SPI operates normally, the data of the SHIFTER register is copied to the receive buffer, and the RDFF flag is set to 1.

② At the end of the serial transfer with the receive buffer full, the SPI detects an overload error and sets the OVRERF flag to 1. SPI will not copy the data of the SHIFTER register to the receive buffer. Even when the PAE bit is 1, a parity error is not detected.

③ Clear the OVRERF flag.

④ Read access to SPI\_DR register allows the SPI to read the data in the receive buffer. The RDFF flag becomes 0. Even if the receive buffer status is empty at this time, the OVRERF flag will not become 0.

⑤ When the serial transmission ends when the OVRERF flag is 1 (overload error), the SPI will not copy the data of the SHIFTER register to the receive buffer, nor will it generate a receive buffer full interrupt, and the RDFF flag will remain at 0. Even if the PAE bit is 1, no parity error is detected. In the state where an overload error occurs, if the serial transmission ends without copying the received data from the SHIFTER register to the receive buffer, the SPI judges that the SHIFTER register is in an empty state and allows data to be transferred from the transmit buffer to the SHIFTER register.

⑥ Normal reception operation can only be performed after the OVRERF flag changes to 0.

Monitoring overload errors can be done by accessing the SPI\_SR register directly or using the SPI error interrupt to access the SPI\_SR register. When performing serial transmission, the occurrence of overload errors must be detected as early as possible by methods such as reading the SPI\_SR register immediately after reading the SPI\_DR register.

In master mode, if the communication automatic suspend function is enabled (set the SPI\_CR.CSUSPE bit to 1), the SPI will suspend the communication clock in the last sampling period before the overload error occurs. At this time, since the SHIFTER register has not completed the reception of the last bit, the SPI remains in the normal communication state and the overload error will not occur. The receive buffer can be read during the communication clock pause. After reading, the receive buffer status becomes empty, and the SPI restarts the communication clock to complete the reception of the last bit of data.

Figure 31-17 Schematic Diagram of Action when Clock Automatic Stop Function Enabled (CPHA=1)

Figure 31-18 Schematic Diagram of Action when Clock Automatic Stop Function Enabled (CPHA=0)

The following describes the running contents of the flags in the time product family shown in figures ①-③:

- ① When the receive buffer is full, the SPI pauses the communication clock before the last bit of data is received. No overload error will occur at this time.
- ② After reading the data in the receive buffer by accessing SPI\_DR, the receive buffer becomes empty, the RDFF flag is cleared, and the SPI restarts the communication clock to complete the last bit of data communication.
- ③ The last bit of data communication is completed, the receive buffer register becomes full again, the RDFF flag is set to 1, and the received data can be read by accessing SPI\_DR.

### 31.3.6.5 Parity Error

When the SPI\_CR.TXMDS bit is 0 and the SPI\_CR.PAE bit is 1, the SPI will perform a parity check at the end of full-duplex synchronous serial communication. When SPI detects a parity error in the received data, set the SPI\_SR.PERF flag to 1. In the SPI\_SR.OVRERF bit 1 state, the received data is not checked for parity errors because SPI does not copy the data of the SHIFTER register to the receive buffer. The PERF flag only can be written to 0 after the SPI\_SR register is read when the PERF flag is 1.

The following figure shows an example of the OVRERF flag and the PERF flag in action. In the example in the figure, the SPI performs 8-bit serial transmission of full-duplex synchronous serial communication when the SPI\_CR.TXMDS bit is 0 and the SPI\_CR.PAE bit is 1.

Figure 31-19 Parity Error

The following describes the running contents of the flags in the time product family shown in figures ① to ③:

① SPI did not detect an overload error and serial delivery ended normally. SPI copies the data of the SHIFTER register to the receive buffer. At this time, SPI performs parity check on the received data. If a parity error is detected, the PERF flag is set to 1.

② Clear the RERF flag.

③ SPI detects an overload error. At this time, SPI does not copy the data of the SHIFTER register to the receiving buffer, SPI does not perform parity check on the data, and no parity check error occurs.

Monitoring parity errors can be done by accessing the SPI\_SR register directly or using the SPI error interrupt to access the SPI\_SR register. When performing serial transmission, the occurrence of parity errors must be detected as early as possible by methods such as reading the SPI\_SR register.

### 31.3.7 SPI Initialization

Write operation or mode fault error detection is used to clear SPE bit, which can inactiveate SPI functions and initialize some SPI functions. If a system reset occurs or the function reset register RMU\_FRST1 is used, all SPI functions are initialized.

#### Initialization by Clear SPE Bit

When the SPI\_CR.SPE bit is set to 0, the SPI performs the following initialization operations:

- Abort in-progress serial delivery.
- If in slave state, stop driving the output signal (the state changes to Hi-Z).
- SPI internal state is initialized.
- Clear transmit buffer, set SPI\_SR.TDEF to 1.

SPI control bits are not initialized by clear SPE bit. As a result, SPI can be started in the same transmission mode as before initialization, as long as SPE is relocated to 1.

Clearing SPE bit does not initialize error flag bits and sequence states. Thus, even after the SPE is cleared, it is possible to confirm the occurrence of errors during SPI transfer by reading the data of the receive buffer.

Clearing SPE bit clears the transmit buffer and sets the SPI\_SR.TDEF to 1. Therefore, if the SPI\_CR.TXIE bit is set to 1 after initialization, an SPI transmit buffer empty interrupt will be generated. To avoid this interrupt, you must clear the SPE bit to 0 while setting the TXIE bit to 0.

## Initialization by Reset

Initialization by system reset or using the function reset register RMU\_FRST1 will initialize all SPI control bits, status bits and data registers. For the contents of the system reset and function reset registers, please refer to the relevant description in the "Reset Module Unit (RMU)" chapter.

### 31.3.8 Interrupt and Events

The SPI receive buffer full, transmit buffer empty, mode fault (overload, underload, parity error) and SPI idle can be used as interrupt sources or internal trigger sources. Transmission completion can only be used as an internal trigger source.

The interrupt of overload, underload and parity errors is integrated into the SPI error interrupt SPEI, so the actual interrupt source needs to be judged by the flag. The specific description of SPI interrupt/internal trigger source is shown in the following table. Once the condition is met, the corresponding interrupt/internal trigger request is generated. For receive buffer full and transmit buffer empty interrupt sources, data transmission changes buffer status to clear.

**Table 31-8 SPI Interrupt Source and Trigger Source Description**

| Interrupt/Internal Trigger Source               | Abbreviation | Interrupt Source | Internal Trigger Source | Condition                                                                                                                                                                                                                                                                |
|-------------------------------------------------|--------------|------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Receive buffer full                             | SPI_SPRI     | √                | √                       | When the receive buffer becomes full while the SPI_CR.RXIE bit is 1                                                                                                                                                                                                      |
| Transmit buffer empty                           | SPI_SPTI     | √                | √                       | When the transmit buffer becomes empty while the SPI_CR.TXIE bit is 1                                                                                                                                                                                                    |
| SPI errors (overload, underload, parity errors) | SPI_SPEI     | √                | √                       | When the SPI_CR.EIE bit is 1, the SPI_SR.OVRERF, SPI_SR.PERF or SPI_SR.MODFERF and SPI_SR.UDRERF flags become 1.                                                                                                                                                         |
| SPI idle                                        | SPI_SPII     | √                | √                       | When the SPI_CR.IDIE bit is 1:<br><ul style="list-style-type: none"> <li>● Master mode: Data transmissions is completed or SPI_CR.SPE is written from 1 to 0.</li> <li>● Slave mode: SPI_CR.SPE is written from 1 to 0.</li> </ul>                                       |
| Data transmission completed                     | SPI_SPEND    | -                | √                       | <ul style="list-style-type: none"> <li>● Master mode: Data transmission completed.</li> <li>● Slave mode: Four-wire, when the SSL pin is at an inactive level; three-wire, when the SCK pin clock reaches the number of clocks required for data transmission</li> </ul> |

The user can write the vectors that can be used as trigger sources in the above table into different trigger object registers to implement various event trigger functions. For the vectors corresponding to the above event trigger sources, please refer to the "Interrupt Event List" in the "Interrupt Controller (INTC) " chapter.

## 31.4 Register Description

### 31.4.1 Register List

- SPI1 base address: 0x4001C000
- SPI2 base address: 0x4001C400
- SPI3 base address: 0x4001C800
- SPI4 base address: 0x40020000
- SPI5 base address: 0x40020400
- SPI6 base address: 0x40020800

Table 31-9 Serial Peripheral Interface (SPI) Register Offset

| Offset | Register                 | Description                                | Width |
|--------|--------------------------|--------------------------------------------|-------|
| 0x00   | <a href="#">SPI_DR</a>   | SPI Data Register                          | 32    |
| 0x04   | <a href="#">SPI_CR</a>   | SPI Control Register                       | 32    |

## 32 Quad Serial Peripheral Interface (QSPI)

### 32.1 Introduction

The Quad Serial Peripheral Interface (QSPI) is a memory control module designed to communicate with serial ROMs with an SPI-compatible interface. Its objects mainly include serial flash memory, serial EEPROM and serial FeRAM.

### 32.2 Features

Table 32-1 QSPI Main Specifications

| Parameters                    | Specifications                                                                                                                                                                                            |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Number of Channels            | 1 channel                                                                                                                                                                                                 |
| SPI                           | Support multiple protocols such as extended SPI, two-wire SPI and four-wire SPI                                                                                                                           |
|                               | SPI mode 0 and SPI mode 3 are supported                                                                                                                                                                   |
|                               | Address line width can be selected from 8 bits/16 bits/24 bits/32 bits                                                                                                                                    |
| Timing Adjustment             | Timing adjustable to support various serial flash                                                                                                                                                         |
| Flash Read                    | Support multiple reading methods:<br>1. Standard Read/Fast Read<br>2. Two-wire output fast read/two-wire input and output fast read<br>3. Four-wire output fast read/four-wire input and output fast read |
|                               | Free setting instruction                                                                                                                                                                                  |
|                               | Adjustable number of dummy periods                                                                                                                                                                        |
|                               | 16-byte read prefetch function                                                                                                                                                                            |
|                               | Status query function                                                                                                                                                                                     |
|                               | SPI bus period extension function                                                                                                                                                                         |
|                               | XIP control Function                                                                                                                                                                                      |
| Direct Communication Function | Flexible and extensive support for a large number of serial flash software control instructions, including erasing, writing, ID reading and power down control, etc.                                      |
| Interrupt Source              | Hardware error interrupt                                                                                                                                                                                  |
| Module Stop Function          | Power consumption can be reduced by module stopping                                                                                                                                                       |

## 32.3 Memory Map

### 32.3.1 Internal Bus Space

The location of the serial flash memory and related control registers in the AHB bus space is determined by the overall address range configuration.

Figure 32-1 Default Area Setting and AHB Bus Space Memory Mapping Relationship Diagram

### 32.3.2 ROM Space and Bus Address Width

QSPI has a 32-bit address bus width to match serial flash memory. Whenever the ROM space of QSPI is read and accessed, the QSPI bus starts to work automatically and transmits the data read from the serial flash memory.

QSPI can not only use 32-bit address bus width, but also select 8-bit/16-bit/24-bit address bus width by setting QSPI\_FCR.AWSL bit.

If the address bus width of 8-bit/16-bit/24-bit is selected, only the low-order space whose address matches it can be accessed normally, that is, accessing the high-order serial flash image space in QSPI will repeatedly appear in the low-order space content.

Figure 32-2 QSPI-ROM Space Memory Image

**Note**

- The address bus width can be selected to use 8 bits/16 bits/24 bits/32 bits by setting QSPI\_FCR.AWSL bit.
- When an 8-bit address width is selected, standard read instructions only support access to the lower 256-byte space, and do not support access to the mirror space.

## 32.4 Functional Description

### 32.4.1 Basic Block Diagram

Figure 32-3 Module Composition Diagram of QSPI

Table 32-2 QSPI pin

| Pin Name | Input/Output | Functional description |
|----------|--------------|------------------------|
| QSPI_SCK | O            | QSPI clock output pin  |
| QSPI_NSS | O            | QSPI slave select pin  |
| QSPI_IO0 | I/O          | Data line 0            |
| QSPI_IO1 | I/O          | Data line 1            |
| QSPI_IO2 | I/O          | Data line 2            |
| QSPI_IO3 | I/O          | Data line 3            |

#### Note

QSPI\_SCK, QSPI\_NSS, QSPI\_IO0, QSPI\_IO1, QSPI\_IO2, and QSPI\_IO3 are hereinafter referred to as QSCK, QSSN, QSI00, QSI01, QSI02, and QSI03 respectively.

### 32.4.2 QSPI Bus

#### 32.4.2.1 SPI Protocol

This QSPI supports three protocols: extended SPI, two-wire SPI and four-wire SPI. The initial default protocol is the extended SPI protocol. The extended SPI protocol only uses the QSI00 pin single-wire for instruction output, and the subsequent addresses and data are output in single-wire/two-wire/four-wire according to the specific read mode instructions.

Figure 32-4 Diagram of Extended SPI Protocol Action 1 (Fast Read Mode)

Figure 32-5 Diagram of Extended SPI Protocol Action 2 (Four-Wire Input/Output Fast Read Mode)

When the QSPI read mode is selected as custom standard read or custom fast read, the protocol of each stage can be configured separately by setting the QSPI\_CR.DPRSL/APRSL/IPRSL bits.

The two-wire SPI protocol uses the two pins QSPI0 and QSPI1 to perform corresponding operations, including sending instructions, addresses, receiving data, and so on.

Figure 32-6 Diagram of Two-wire SPI Protocol Action (Fast Read Mode)

The four-wire SPI protocol uses four pins QSI00, QSI01, QSI02, and QSI03 to perform all related operations such as sending instructions, addressing, and receiving data.

Figure 32-7 Diagram Four-Wire SPI Protocol Action (Fast Read Mode)

### 32.4.2.2 SPI Mode

There are two SPI modes, Mode 0 and Mode 3, and the mode switching can be realized by setting the QSPI\_CR.SPIMD3 bit. The difference between SPI mode 0 and mode 3 is the different levels of QCK in the idle state. In SPI mode 0, the idle state level of QCK is low level, while in mode 3, the idle state level is high level.

Serial data is output from the QSPI on the falling edge of the serial clock and read into the external flash memory on the rising edge. The external flash memory outputs serial data at the falling edge of the serial clock and is read in by QSPI at the falling edge of the next clock.

Figure 32-8 Basic Timing Diagram of Serial Interface

### 32.4.3 Timing Adjustment of QSPI Bus

The timing of QSPI bus signals can be fine-tuned through registers, and the timing after fine-tuning can be better applied to various QSPI bus accesses, whether it is ROM access mode or direct communication mode.

### 32.4.3.1 QSPI Bus Reference Clock

The reference clock of the QSPI bus is obtained by HCLK after frequency division. By setting the QSPI\_CR.DIV bit, various clock sources such as HCLK divided by 2 to 64 can be selected as the reference clock of the QSPI bus.

### 32.4.3.2 QSPI Communication Clock Duty Cycle Correction

When the reference clock selects an even multiple frequency division of HCLK, the high and low level times of the QSCK signal are consistent. If an odd multiple frequency division is selected, the high level time of the QSCK signal will be one HCLK period longer than the low level.

If you want QSCK to output a clock signal with a duty cycle of about 50% when selecting an odd frequency division, you can set the QSPI\_FCR.DUTY bit to 1. Through this setting, the output time of the rising edge of the QSCK signal will be half a HCLK period later than before the adjustment, and the output time of the falling edge remains unchanged. Thus, a QSCK signal with a duty cycle of 50% can be obtained. When the base clock is divided by an even multiple of HCLK, please set the DUTY bit to 0. In the initial state, the DUTY bit defaults to 1.

Figure 32-9 Diagram of Output Clock Duty Cycle Correction when HCLK is Divided by 3 as the Reference Clock

### 32.4.3.3 QSSN Signal Minimum High-level width

In order to meet the cancellation time requirement required by the serial flash memory, the QSSN signal must maintain a high level state (that is, an idle state) for a long enough time between two adjacent QSPI bus periods. The minimum high width of QSSN can be selected by setting the QSPI\_CSCR.SSHW bits, ranging from 1 to 16 QSPI reference clock periods.

### 32.4.3.4 QSSN Establishment Time

The time from when the QSSN signal starts to output a low level (that is, becomes a active state) to when the QSCK signal outputs the first edge is called the QSSN setup time, which can be configured through register settings to meet the requirements of the external serial flash memory. Set the QSPI\_FCR.SSNLD bit to select whether the QSSN setup time is 0.5 or 1.5 QSPI reference clock periods. This setting can also be used to configure the setup time of the data pin from data output permission to the first edge of the QSCK signal output, which can be used reasonably as needed.

Figure 32-10 QSSN Setup Time Configuration Diagram

### 32.4.3.5 QSSN Hold Time

The time between the last rising edge of QSCCK signal output and the start of QSSN signal output high level (that is, becomes idle state) is called the hold time of QSSN, which can be configured through register settings to meet the requirements of external devices. Set the QSPI\_FCR.SSNHD bit to select whether the QSSN hold time is 0.5 or 1.5 QSPI reference clock periods.

Figure 32-11 QSSN Hold Time Configuration Diagram

### 32.4.3.6 Serial Data Receive Delay

The data of the serial flash memory is output synchronously with the falling edge of QSCCK, and the QSPI receives the data on the next falling edge of QSCCK. The period from when the serial flash starts outputting data to when the data is received by QSPI is called receive latency. QSPI adds a delay adjustment period before the first data receive period. From the perspective of serial flash memory, this period can be regarded as an increase in the counterparty data receiving period. This delay adjustment period will only be generated when data is received.

Figure 32-12 Diagram of Data Receiving Delay

### 32.4.4 Introduction to SPI Instructions for ROM Access

#### 32.4.4.1 Existing QSPI-ROM Instruction Reference

Table 32-3 Reference Instruction List

| Mode Name            |                                     | Instruction Code | Description |
|----------------------|-------------------------------------|------------------|-------------|
| 4-Bytes Address Mode | Standard read                       | 0x13             | -           |
|                      | Fast read                           | 0x0C             | -           |
|                      | Two-wire output fast read           | 0x3C             | -           |
|                      | Two-wire input and output fast read | 0xBC             | -           |
|                      | Four-wire output fast read          | 0x6C             | -           |
|                      | Four-wire input output fast read    | 0xEC             | -           |
|                      | Exit 4-Bytes mode                   | 0xE9             | -           |
| 3-Bytes Address Mode | Standard read                       | 0x03             | -           |
|                      | Fast read                           | 0x0B             | -           |
|                      | Two-wire output fast read           | 0x3B             | -           |
|                      | Two-wire input and output fast read | 0xBB             | -           |
|                      | Four-wire output fast read          | 0x6B             | -           |
|                      | Four-wire input output fast read    | 0xEB             | -           |
|                      | Enter 4-Bytes mode                  | 0xB7             | -           |
| -                    | Write mode                          | 0x06             | -           |

When the serial flash memory performs "custom standard read" and "custom fast read" access, the instruction needs to be set through the instruction register QSPI\_CCMD.

#### 32.4.4.2 Standard Read Instruction

The standard read instruction is a common read instruction supported by most serial flash memory. When a serial bus period starts, the serial flash select signal is set to the active state, and then QSPI outputs the instruction code (0x03/0x13) of the instruction, followed by the target address. The width of the address can be set by the QSPI\_FCR.AWSL bit. Then the data can be received. The instruction selected by the initial state of QSPI is the standard read instruction.

Figure 32-13 Diagram of a Standard Read Bus Cycle

#### 32.4.4.3 Fast Read Instruction

The fast read instruction is a read instruction that supports a faster communication clock. When a serial bus period starts, the serial flash select signal is set to the active state, and then QSPI outputs the instruction code (0x0B/0x0C) of the instruction, followed by the target address. The address width can be set by the QSPI\_FCR.AWSL bit. The address output is followed by a certain number of dummy periods, the specific number of which is determined by QSPI\_FCR.DMCYCN bit. Next is the reception of data.

The first two periods of the dummy period are used to decide whether to select XIP mode. When XIP mode is selected, the instruction used in this transmission will be applied to the next SPI bus period, and the instruction transmission part will be omitted in the next SPI bus period. For details, see "XIP Control".

Figure 32-14 Fast Read Bus Cycle Diagram

Figure 32-15 Fast Read Bus Cycle for Selecting XIP Mode Diagram

**Note**

To use the fast read instruction, make sure to use a serial flash that supports the fast read function.

### 32.4.4.4 Two-wire Output Fast Read Instruction

Two-wire output fast read is a read instruction that uses two signal lines for data reception. When a serial bus period starts, the serial flash select signal is set to the active state, and QSPI starts to output the instruction code (0x3B/0x3C) and target address of the instruction from the QSI00 pin. The address width can be set by the QSPI\_FCR.AWSL bit. This is followed by a certain number of dummy periods, the specific number of which is determined by QSPI\_FCR.DMTCYCN bit. Then start to receive data through the two pins QSI00 and QSI01. Even-numbered bit data is received at QSI00 and odd-numbered bit at QSI01.

The first two periods of the dummy period are used to decide whether to select XIP mode. When XIP mode is selected, the instruction used in this transmission will be applied to the next QSPI bus period, and the instruction transmission part will be omitted in the next QSPI bus period. For details, see "[XIP Control](#)".

Figure 32-16 Two-Wire Output Fast Read Bus Cycle Diagram

Figure 32-17 Two-Wire Output Fast Read Bus Cycle for Selecting XIP Mode Diagram

#### Note

To use the two-wire output fast read instruction, please make sure to use a serial flash memory that supports this function.

### 32.4.4.5 Two-wire Input and Output Fast Read Instruction

Two-wire input and output fast read is a read instruction that uses two signal lines for sending and data reception. When a serial bus period starts, the serial flash select signal is set to the active state, and the QSPI starts outputting the instruction code (0xBB/0xBC) of the instruction from the QSIO0 pin. After that, QSPI outputs the target address from the QSIO0 and QSIO1 pins. The address width can be set by the QSPI\_FCR.AWSL bit. This is followed by a certain number of dummy periods, the specific number of which is determined by QSPI\_FCR.DMCYCN bit. Then start to receive data through the two pins QSIO0 and QSIO1. The transmission and data reception of even-numbered addresses and dummy periods (including XIP mode selection information) use QSIO0 pins, and odd-numbered bits use QSIO1 pins.

The first two periods of the dummy period are used to decide whether to select XIP mode. When XIP mode is selected, the instruction used in this transmission will be applied to the next QSPI bus period, and the instruction transmission part will be omitted in the next QSPI bus period. For details, see "[XIP Control](#)".

Figure 32-18 Two-Wire Input and Output Fast Read Bus Cycle Diagram

Figure 32-19 Two-Wire Input and Output Fast Read Bus Cycle for Selecting XIP Mode Diagram

#### Note

To use the two-wire input and output fast read instruction, please make sure to use a serial flash memory that supports this function.

### 32.4.4.6 Four-wire Output Fast Read Instruction

Four-wire output fast read is a read instruction that uses four signal lines for data reception. When a serial bus period starts, the serial flash select signal is set to the active state, and QSPI starts to output the instruction code (0x6B/0x6C) and target address of the instruction from the QSI00 pin. The address width can be set by the QSPI\_FCR.AWSL bit. This is followed by a certain number of dummy periods, the specific number of which is determined by QSPI\_FCR.DMCYCN bit. Then start to receive data through the four pins QSI00, QSI01, QSI02 and QSI03.

The first two periods of the dummy period are used to decide whether to select XIP mode. When XIP mode is selected, the instruction used in this transmission will be applied to the next SPI bus period, and the instruction transmission part will be omitted in the next SPI bus period. For details, see "XIP Control".

Figure 32-20 Four-Wire Output Fast Read Bus Cycle Diagram

Figure 32-21 Four-Wire Output Fast Read Bus Cycle for Selecting XIP Mode Diagram

#### Note

To use the 4-wire output fast read instruction, make sure to use a serial flash that supports this feature.

### 32.4.4.7 Four-wire Input and Output Fast Read Instruction

Four-wire input and output fast read is a read instruction that uses four signal lines for address transmission and data reception. When a serial bus period starts, the serial flash select signal is set to the active state, and the QSPI starts outputting the instruction code (0xEB/0xEC) of the instruction from the QSI00 pin. After that, QSPI outputs the target address from the four pins QSI00, QSI01, QSI02 and QSI03. The address width can be set by the QSPI\_FCR.AWSL bit. This is followed by a certain number of dummy periods, the specific number of which is determined by QSPI\_FCR.DMCYCN bit. Then start to receive data through the four pins QSI00, QSI01, QSI02 and QSI03.

The first two periods of the dummy period are used to decide whether to select XIP mode. When XIP mode is selected, the instruction used in this transmission will be applied to the next QSPI bus period, and the instruction transmission part will be omitted in the next QSPI bus period. For details, see "[XIP Control](#)".

Figure 32-22 Four-Wire Input and Output Fast Read Bus Cycle Diagram

Figure 32-23 Four-Wire Input and Output Fast Read Bus Cycle for Selecting XIP Mode Diagram

#### Note

To use the four-wire input and output fast read instruction, make sure you use a serial flash memory that supports this feature.

### 32.4.4.8 Enter 4-Bytes Mode Instruction

The instruction to enter 4-Bytes mode can set the address width of the serial flash memory to 4 bytes. When a serial bus period starts, the serial flash select signal is asserted, and the QSPI starts to output the instruction code (0xB7) of the instruction from the QSI00 pin.

Figure 32-24 Diagram of Instruction Bus Cycle when Entering 4-Bytes Mode

#### Note

This instruction can be issued regardless of whether the serial flash memory is in 4-Bytes or 3-Bytes Mode.

### 32.4.4.9 Exit 4-Bytes Mode Instruction

The instruction to exit 4-Bytes mode can set the address width of the serial flash memory to 3 bytes. When a serial bus period starts, the serial flash select signal is set to the active state, and the QSPI starts to output the instruction code (0xE9) of the instruction from the QSI00 pin.

Figure 32-25 Exit 4-Byte Mode Instruction Bus Period Diagram

#### Note

This instruction can be issued regardless of whether the serial flash memory is in 4-Bytes or 3-Bytes Mode.

### 32.4.4.10 Write Mode Instruction

The write mode instruction allows the serial Flash memory to be written. When a serial bus period starts, the serial flash select signal is set to the active state, and the QSPI starts to output the instruction code (0x06) of the instruction from the QSI00 pin.

Figure 32-26 Diagram of Write Mode Instruction Bus Period

## 32.4.5 Scheduling of QSPI Bus Period

### 32.4.5.1 Single Flash Read with Independent Conversion

A single read instruction for ROM will be independently converted one-to-one from the internal bus period of the chip to the QSPI bus period. When a ROM read bus period is detected, the QSSN signal is set to the active state to initiate a QSPI bus period. After receiving the data from the serial flash memory, the QSSN signal becomes inactive, and the QSPI bus period is declared complete.

When another ROM read bus period is detected, the QSSN signal will be set to an active state again after ensuring that the inactive hold time has exceeded the minimum inactive hold width, and a new QSPI bus period begins.

Figure 32-27 Diagram of Single Flash Memory Data Read Operation with Independent Conversion

### 32.4.5.2 Flash Read Using Pre-fetch

For the transfer of CPU instructions or data blocks, the system usually reads data in a sequentially increasing flash memory address sequence. Serial flash memory has continuous data transfer capability without sending instruction codes and addresses again. However, if the internal bus period released by the MCU is converted independently, the QSPI bus period is also divided into independent individuals,

resulting in the inability to actively utilize the advantages of continuous data transmission of the serial flash memory. In this regard, QSPI provides a pre-fetch function for continuous data reception.

The pre-fetch function is activated by setting the QSPI\_CR.PFE bit to 1. When this function is enabled, data will be continuously received and stored in the buffer without waiting for another flash read request. When the MCU issues a flash read operation, the QSPI will match the access address. If the match is successful, the data in the buffer at the corresponding position will be transmitted to the MCU. If the match fails, the data in the buffer will be discarded and a new QSPI bus period will be reissued.

The pre-fetch buffer can store a maximum of 16 bytes of data. In addition, there is a 2-byte data receiving buffer that can also store pre-fetch data. When all the buffer data is full, The QSPI bus period ends. When the buffer data is read and a new buffer space is generated, QSPI will automatically start a new QSPI bus period to resume the pre-fetch action.

Figure 32-28 Diagram of Data Reading Operation when Pre-fetch Function Enable

### 32.4.5.3 Pre-fetch Termination

If a ROM read bus period to other addresses of the serial flash memory occurs during the pre-fetch transfer, the original pre-fetch action will be terminated and a new QSPI bus period will start. Normally, the pre-fetch operation will be terminated after the current byte transmission is completed, but if the QSPI\_CR.PFSAE bit is set to 1, QSPI will immediately stop the pre-fetch operation without waiting until the current byte transmission is completed. Use of this feature requires the serial flash device to support the instant stop action feature.

### 32.4.5.4 Pre-fetch Status Monitoring

Reading data from a low-speed serial flash memory will increase the load on the system, because the internal bus needs to be in a waiting state until the QSPI bus period of the receiving signal is completed. QSPI provides pre-fetch status monitoring to reduce this load.

The QSPI\_SR.PFAN bit shows the current pre-fetch working status, the QSPI\_SR.PFFUL bit indicates that the pre-fetch data buffer is full, and QSPI\_SR.PFNUM bit shows that the buffer has been read the number of bytes of data in the zone. Through these status bits, it is convenient to determine the current pre-fetch status through a CPU instruction.

#### Note

When executing a pre-fetch status monitoring program, place the program code outside the target serial flash area or enable instruction cache. Otherwise, the pre-fetch object will frequently switch between the object data area and the instruction area, losing the meaning of pre-fetch, and the monitoring program will enter an infinite loop because the pre-fetch cannot be completed.

### 32.4.5.5 Flash Read Using QSPI Bus Cycle Stretching

If the QSPI\_CSCR.SSNW bit is set to a value other than 0b00, the QSPI bus period will be in a hold state after receiving the data and wait for the next data to be read. At this time, the QSSN signal will remain in a low-level active state, while the QSCK is in a stopped state. If the next flash memory read instruction arrives, if the address of the read object is sequentially incremented next to the current address, QSPI will restart QSCK and directly accept data. If it is a discontinuous address, the QSSN signal will be set to a high-level inactive state to end the previously maintained QSPI bus period, and then start a new SPI bus period.

This function can prevent the system from repeatedly sending instruction codes and addresses when performing discontinuous reading of continuously increasing addresses, thereby improving reading efficiency.

The extension time of the QSPI bus period can be set by QSPI\_CSCR.SSNW. When the next reading does not occur after the set time, QSSN will be automatically set to a high-level inactive state to end the QSPI bus period. If QSPI\_CSCR.SSNW is set to 0b11, the QSSN will be extended indefinitely, and the QSPI bus period will always be in the hold state, but this will increase the power consumption of the serial flash memory.

Figure 32-29 Diagram of Data Read Operation by QSPI Bus Cycle Extension Function

## 32.4.6 XIP Control

### 32.4.6.1 XIP Mode Overview

Some serial flash devices can reduce latency by omitting to receive a read instruction. This function is selected by a mode code sent during the dummy period.

During dummy periods at fast speed instructions, QSPI controls the XIP mode of the serial flash by sending XIP mode codes during the first two periods. Different serial flash memories have different XIP mode codes, which can be set specifically through the QSPI\_XCMD.XIPMC bit. Please refer to the figure below for details.

Figure 32-30 XIP Mode Control Diagram

### 32.4.6.2 XIP Mode Setting

When the XIP mode code of the corresponding serial flash memory is written to `QSPI_XCMD.XIPMC` and the `QSPI_CR.XIPE` bit is set to 1, when the next fast read instruction occurs, the set mode code will be transmitted to the target serial flash memory during the first two periods of the virtual period. After the mode code is received, the serial flash memory and its control part will start the XIP mode. Whether the system has entered XIP mode can be confirmed by checking the `QSPI_SR.XIPF` bit.

#### Note

To enable the XIP mode of the serial flash memory, the corresponding mode code must be set in `QSPI_XCMD.XIPMC`. However, for the control part, XIP mode can be enabled simply by setting the `XIPE` bit to 1, regardless of the value in `QSPI_XCMD.XIPMC`.

### 32.4.6.3 Exit From XIP Mode

When the exit XIP mode code of the corresponding serial flash memory is written to `QSPI_XCMD.XIPMC` and the `QSPI_CR.XIPE` bit is set to 0, when the next fast read instruction occurs, the set exit mode code will be transmitted to the target serial flash during the first two periods of the dummy period. After the exit mode code is received, the serial flash memory and its control part will exit the XIP mode. Whether the system has exited XIP mode can be confirmed by checking the `QSPI_SR.XIPF` bit.

**Note**

To exit the XIP mode of the serial flash memory, the corresponding exit mode code must be set in QSPI\_XCMD.XIPMC. However, for the control part, XIP mode can be disabled simply by setting the XIPE bit to 0, regardless of the value in QSPI\_XCMD.XIPMC.

### 32.4.7 Pin Status of QSI02 and QSI03

The state of the QSI02 and QSI03 pins depends on the serial read mode set by the MDSEL[2:0] bits in the QSPI\_CR register.

Table 32-4 Pin Status of QSI02 and QSI03

| QSPI_CR.MDSEL | QSI02 Status                                                                                                | QSI03 Status                                                        | Remark                              |
|---------------|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|-------------------------------------|
| 0b000         | Output status, the output level is determined by the QSPI_FCR.WPOL bit, and the initial output is low level | Output high level                                                   | Standard read (initial status)      |
| 0b001         |                                                                                                             |                                                                     | Fast read                           |
| 0b010         |                                                                                                             |                                                                     | Two-wire output fast read           |
| 0b011         |                                                                                                             |                                                                     | Two-wire input and output fast read |
| 0b100         | As the third data line for input or output, the idle state is Hi-Z                                          | As the fourth data line for input or output, the idle state is Hi-Z | Four-wire output fast read          |
| 0b101         |                                                                                                             |                                                                     | Four-wire input output fast read    |
| 0b110         | Refer to the specific protocol settings for each stage                                                      | Refer to the specific protocol settings for each stage              | Custom protocol standard read       |
| 0b111         |                                                                                                             |                                                                     | Custom protocol fast read           |

**Note**

- The QSI02 pin can also be used as the WP# function of the serial flash.
- The QSI03 pin can also be used as the HOLD# or RESET# function of the serial flash.

### 32.4.8 Direct Communication Mode

#### 32.4.8.1 About Direct Communication Mode

QSPI can read serial flash memory by automatically converting the MCU's external ROM read bus period to QSPI bus period. But the serial flash memory also has many different additional functions, such as ID information reading, erasing, writing, and status information reading. These functions do not have a set of standard instructions to set, and with the rapid increase of new functions of serial flash memory, the correspondence at the hardware level becomes more and more difficult.

In response to this situation, QSPI provides a direct communication mode, and users can directly control the serial flash memory through software. This mode software can generate any desired QSPI bus period.

### 32.4.8.2 Direct Communication Mode Setting

Setting the QSPI\_CR.DCOME bit to 1 can enter direct communication mode. Once it enters the direct communication mode, it will not be able to perform normal flash memory read operations. If you want to perform regular flash memory read operations, you need to clear the DCOME bit to exit the direct communication mode.

**Note**

If the system is in XIP mode, it is necessary to exit the XIP mode first before activating the direct communication mode.

### 32.4.8.3 QSPI Bus Period Generation in Direct Communication Mode

A complete QSPI bus period in direct communication mode starts from the first operation on the QSPI\_DCOM register and ends after a write operation on the QSPI\_CR register. During this period, QSPI\_DCOM.DCOMPRSL and QSPI\_DCOM.DCOM can be operated multiple times.

Direct communication mode does support multi-line actions.

- When DCOMPRSL[1:0] is set to 0b00, the write of DCOM[7:0] is converted into a single-byte data transmission of the QSPI bus extended SPI protocol, and the read of DCOM[7:0] is converted into a single-byte data reception of the QSPI bus extended SPI protocol.
- When DCOMPRSL[1:0] is set to 0b01, the write of DCOM[7:0] is converted into a single-byte data transmission of the QSPI bus two-wire SPI protocol, and the read of DCOM[7:0] is converted into a single-byte data reception of the QSPI bus two-wire SPI protocol.
- When DCOMPRSL[1:0] is set to 0b10, the write of DCOM[7:0] is converted into a single-byte data transmission of the QSPI bus four-wire SPI protocol, and the read of DCOM[7:0] is converted into a single-byte data reception of the QSPI bus four-wire SPI protocol.

From the first operation on the QSPI\_DCOM register to the last write operation on the QSPI\_CR register, the QSSN signal always remains in a active low state.

**Note**

- Writing to any QSPI register other than QSPI\_DCOM in direct communication mode will exit direct communication mode. Exiting direct communication mode by any method other than "QSPI\_CR register write operation" may cause unexpected situations, so it is not recommended.
- In direct communication mode, one-wire, two-wire or four-wire mode can be freely switched by rewriting DCOMPRSL[1:0]. If the line mode needs to be switched before the direct read operation, please note that writing DCOMPRSL[1:0] will result in a dummy data transmission.
- When writing to the QSPI\_DCOM register, you must use 32-bit or 16-bit operations and write to both the DCOMPRSL[1:0] and DCOM[7:0] bits. When reading the QSPI\_DCOM register, 32-bit, 16-bit, or 8-bit operations can be used.

### 32.4.9 Interrupt

When a read access operation to the ROM is detected in direct communication mode, the QSPI\_SR.RAER bit is set to 1, and the QSPI will generate a bus hardware error interrupt. The interrupt request will be held until the RAER bit is cleared. For more information, refer to "Interrupt Controller (INTC)" chapter.

## 32.5 Register Description

### 32.5.1 Register List

QSPI base address: 0x9C000000

Table 32-5 Quad Serial Peripheral Interface (QSPI) Register Offset

| Offset | Register                  | Description                                    | Width |

## 32.6 Precautions

### 32.6.1 QSPI Registers Setting

If the QSPI control register is dynamically set or changed during QSPI communication, it may cause new communication to start before the register is fully set. Therefore, it is not recommended to dynamically modify the QSPI control register during communication.

### 32.6.2 Module Stop Bit Settings

QSPI is in the module stop state after system reset. When the QSPI module is required to work, please clear the QSPI module control bit in the PWC\_FCG register first. For specific descriptions, please refer to the relevant sections of the "Action Mode and Low Power Mode" chapter in the "Power Control (PWC) " chapter.

## 33 Inter\_IC Sound Bus (I2S)

### 33.1 Introduction

I2S (Inter\_IC Sound Bus), integrated circuit built-in sound bus, which is dedicated to data transmission between sound devices.

### 33.2 Features

Table 33-1 I2S Main Features

| Function             | Main Features                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

33.3.2 Pin Description

Table 33-2 I2S Pin Description

| Pin Name | Direction    | Function Description                                                                                                            |
|----------|--------------|---------------------------------------------------------------------------------------------------------------------------------|
| I2Sn_CK  | Input/Output | Serial clock, which is the serial clock output in master mode and the serial clock input in slave mode.                         |
| I2Sn_WS  | Input/Output | Word selection, which is the data control signal output in the master mode and the data control signal input in the slave mode. |

| Pin Name  | Direction    | Function Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I2Sn_SD   | Input/Output | Serial data, for half-duplex mode data input, or half/full-duplex mode data output.                                                                                                                                                                                                                                                                                                                                         |
| I2Sn_SDIN | Input        | Full-duplex audio data input. Pin used for serial data input in I2S full-duplex mode.                                                                                                                                                                                                                                                                                                                                       |
| I2Sn_EXCK | Input        | The external clock source is that the clock generator in the master mode selects an external clock as the divided clock source.                                                                                                                                                                                                                                                                                             |
| I2Sn_MCK  | Output       | Drive clock, when I2S is configured as master mode (and MCKOE bit is set to 1), use the drive clock (separate mapping) to output this additional clock. The clock output frequency is $256 \times F_s$ , where $F_s$ is the audio signal sampling frequency. I2S uses its own clock generator to generate the communication clock in the master mode. This clock generator is also the source that drives the clock output. |

**Note**

The value of n is 1-4.

### 33.3.3 Communication Method

It supports half-duplex and full-duplex communication modes, which can be selected through the I2S\_CTRL.DUPLEX bit.

- When the I2S\_CTRL.DUPLEX bit is 0, I2S operates in the half-duplex communication mode, uses the I2Sn\_SD pin as the output data pin when only sending, and uses the I2Sn\_SD pin as the input data pin when only receiving.
- When the I2S\_CTRL.DUPLEX bit is 1, I2S operates in full-duplex communication mode. At this time, the I2Sn\_SDIN pin is used as the input data pin, and the I2Sn\_SD pin is used as the output data pin to realize full-duplex communication.

### 33.3.4 Supported Audio Protocols

#### 33.3.4.1 Audio Protocol Overview

There are four data and frame format combinations to send data in the following formats:

- 16-bit data encapsulated in 16-bit frame
- 16-bit data encapsulated in 32-bit frame
- 24-bit data encapsulated in 32-bit frame
- 32-bit data encapsulated in 32-bit frame

When using 16 bits of data in a 32-bit frame, the first 16 bits (MSB) are valid and the 16 LSB are forced to 0 without any software action (just one read/write operation).

When using 24 bits of data in a 32-bit frame, the first 24 bits (MSB) are valid and the 8 LSB are forced to 0 without any software action (just one read/write operation).

For all data formats and communication standards, the most significant bit is always sent first (MSB first).

The I2S interface supports 4 audio protocols, which can be configured using the I2S\_CFGR.I2SSTD and I2S\_CFGR.PCMSYNC bit.

### 33.3.4.2 I2S Philips Standard

Use the WS signal to indicate which channel the data currently being sent belongs to. This signal is enable one clock before the first bit (MSB) of the current channel's data.

Figure 33-2 I2S Philips Protocol Waveform (16/32 bit Full Precision)

16 bits are encapsulated in a 16-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x3344; in receive mode, SD inputs serial data 0xEEDD, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-3 I2S Philips Protocol Waveform (16-bit Data Encapsulated in 32-bit Frame)

16 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x33440000; in receive mode, SD inputs serial data 0xEEDDXXXX, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-4 I2S Philips Protocol Waveform (24-bit Data Encapsulated in 32-bit Frame)

24 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFF223344, SD outputs serial data 0x22334400; in receive mode, SD inputs serial data 0xEEDD11XX, and I2S\_RXBUF register reads data 0x00EEDD11.

### 33.3.4.3 MSB Alignment Standard

This standard generates both the WS signal and the first data bit (ie MSBit).

Figure 33-5 I2S MSB Protocol Waveform (16/32-bit Full Precision)

The sender changes data on the falling edge of the clock signal; the receiver reads data on the rising edge.

16 bits are encapsulated in a 16-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x3344; in receive mode, SD inputs serial data 0xEEDD, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-6 I2S MSB Protocol Waveform (16-bit Data Encapsulated in 32-bit Frame)

16 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x33440000; in receive mode, SD inputs serial data 0xEEDDXXXX, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-7 I2S MSB Protocol Waveform (24-bit Data Encapsulated in 32-bit Frame)

24 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFF223344, SD outputs serial data 0x22334400; in receive mode, SD inputs serial data 0xEEDD11XX, and I2S\_RXBUF register reads data 0x00EEDD11.

#### 33.3.4.4 LSB Alignment Standard

This standard is similar to the MSB alignment standard (for 16-bit and 32-bit full-precision frame formats, there is no difference).

**Figure 33-8 I2S LSB Protocol Waveform (16/32-bit Full Precision)**

16 bits are encapsulated in a 16-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x3344; in receive mode, SD inputs serial data 0xEEDD, and I2S\_RXBUF register reads data 0x0000EEDD.

**Figure 33-9 I2S LSB Protocol Waveform (16-bit Data Encapsulated in 32-bit Frame)**

16 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x00003344; in receive mode, SD inputs serial data 0xFFFF1122, and I2S\_RXBUF register reads data 0x00001122.

**Figure 33-10 I2S LSB Protocol Waveform (24-bit Data Encapsulated in 32-bit Frame)**

24 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFF223344, SD outputs serial data 0x00223344; in receive mode, SD inputs serial data 0xFFDD1122, and I2S\_RXBUF register reads data 0x00DD1122.

### 33.3.4.5 PCM Standard

For the PCM standard, there is no need to use channel information. There are two PCM modes (Short Frame and Long Frame) and are configurable using the in I2S\_CFGR.PCMSYNC bit.

Figure 33-11 I2S PCM Protocol Waveform (16/32-bit Full Precision)

For long frame synchronization, the WS signal is maintained for 13 periods in master mode.

For short frame synchronization, the duration of the WS synchronization signal is only one period.

16 bits are encapsulated in a 16-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x3344; in receive mode, SD inputs serial data 0xEEDD, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-12 I2S PCM Protocol Waveform (16-bit Data Encapsulated in 32-bit Frame)

16 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xFFFF3344, SD outputs serial data 0x00003344; in receive mode, SD inputs serial data 0xEEDDXXXX, and I2S\_RXBUF register reads data 0x0000EEDD.

Figure 33-13 I2S PCM Protocol Waveform (24-bit Data Encapsulated in 32-bit Frame)

24 bits are encapsulated in a 32-bit frame. In transmit mode, write to I2S\_TXBUF register 0xXX223344, SD outputs serial data 0x00223344; in receive mode, SD inputs serial data 0xEEDD11XX, and I2S\_RXBUF register reads data 0x00EEDD11.

#### Note

For two modes (master/slave mode) and two synchronizations (short/long synchronization), even in slave mode, it need to specify the number of bits (I2S\_CFGR.DATLEN bit and I2S\_CFGR.CHLEN bit in I2S\_CFGR register) between two sets of continuous data (and two synchronization signals).

### 33.3.5 Clock Generator

The I2S bit rate is used to determine the data flow on the I2S data line and the I2S clock signal frequency.

I2S bit rate=number of bits per channel×number of channels×audio sampling frequency

For 16-bit dual-channel audio, the calculation formula of I2S bit rate is as follows: I2S bit rate=16×2×Fs.  
If the frame is 32 bits wide, then the I2S bit rate=32×2×Fs.

Figure 33-14 Audio Sampling Frequency Definition

When configuring master mode, the linear divider needs to be set up correctly to communicate at the desired audio frequency.

Figure 33-15 Clock Generator Architecture

The clk clock source can be I2SCLK output or external clock.

The audio sampling frequency may be 192kHz, 96kHz or 48kHz etc. To achieve the desired frequency, the current divider needs to be programmed according to the following formula:

- **When output drive clock (mckoe is set to 1) :**

$F_s = \text{clk} / [(16 \times 2) * ((2 * I2SDIV + ODD) * 8)]$  (when the channel frame width is 16 bits)

$F_s = \text{clk} / [(32 \times 2) * ((2 * I2SDIV + ODD) * 4)]$  (when the channel frame width is 32 bits)

- **When turn off drive clock (mckoe is cleared) :**

$F_s = \text{clk} / [(16 \times 2) * (2 * I2SDIV + ODD)]$  (when the channel frame width is 16 bits)

$F_s = \text{clk} / [(32 \times 2) * (2 * I2SDIV + ODD)]$  (when the channel frame width is 32 bits)

The table below provides example accuracy values for different clock configurations. There are other configurations that achieve better clock accuracy.

**Table 33-3 Audio Frequency Accuracy (For VCO Input Frequency=1MHz)**

| Drive Clock     | Target Fs (Hz) | Data Format | Frequency Multiplication Coefficient | Output Division Ratio | I2SDIV | ODD | Real-time fS(Hz) | Error   |
|-----------------|----------------|-------------|--------------------------------------|-----------------------|--------|-----|------------------|---------|
| Output Disabled | 8000           | 16-bit      | 288                                  | 3                     | 187    | 1   | 8000             | 0.0000% |
|                 |                | 32-bit      | 256                                  | 4                     | 62     | 1   | 8000             | 0.0000% |

|                 | 22050          | -           | 429                                  | 4                     | 9      | 1   | 22049.75291      | 0.0011% |
|                 | 44100          | -           | 271                                  | 2                     | 6      | 0   | 44108.07422      | 0.0183% |

#### Note

The frequency multiplication coefficient can be PLLAN/PLLHN, when the frequency multiplication coefficient is PLLAN, the output frequency division ratio can be PLLAP/PLLAQ/PLLAR, and when the frequency multiplication coefficient is PLLHN, the output frequency division ratio can be PLLHP/PLLHQ/PLLHR. For specific settings, refer to "CMU PLLA Configuration Register (CMU\_PLLACFGR)" and "CMU PLLH Configuration Register (CMU\_PLLHCFGR)" of the "Clock Module Unit (CMU)" chapter.

## 33.3.6 Master/Slave Mode

### 33.3.6.1 I2S Master Mode

I2S can be configured as follows:

- Transmit master or receive master (using I2S half-duplex mode).
- Simultaneous transmit and receive master (using I2S full-duplex mode).

I2S works in the master mode, the serial clock is output by the pin CK, and the word selection signal is generated by the pin WS. It can choose to output or not output the drive clock (MCK) by setting the I2S\_CTRL.MCKOE bit.

**Steps:**

- Step1.** Set the pins that I2S needs to use.
- Step2.** Select the clock source through the I2S\_CTRL.CLKSEL, I2S\_CTRL.I2SPLLSEL bit.
- Step3.** Set the I2S\_PR.I2SDIV bit and the I2S\_CTRL.ODD bit to define the serial data baud rate for proper audio sampling frequency.
- Step4.** Set the I2S\_CFGR register, select the I2S standard through the I2SSTD and PCMSYNC bit, select the data length through the DATLEN bit and select the number of bits per channel by configuring the CHLEN bit.
- Step5.** If it need to use interrupt, set the interrupt register of the system.
- Step6.** If it need to use DMA, set the relevant register for DMA.
- Step7.** Set I2S\_CTRL register, including working mode setting, communication mode setting, clock output permission setting, data output permission setting, FIFO reset setting, sending/receiving buffer threshold setting, etc., working mode WMS bit select I2S master mode.
- Step8.** Set the interrupt permission bit.
- Step9.** Set I2S\_CTRL.TXE and I2S\_CTRL.RXE, and the action starts.

**Note**

When using TXIRQOUT interrupt to write communication data to TXBUF, if each interrupt writes two data, first turn off the transmit interrupt enable flag TXIE after the interrupt starts, and then enable TXIE after writing the data. Or write only one data per interrupt.

**Transmit Sequence**

The I2S\_CTRL.TXE bit is set to 1 to enable transmission. The transmit sequence begins as soon as the data is written to the transmit buffer. A complete frame means that the left channel data is sent first and then the right channel data is sent. There are no partial frames where only the left channel is sent. During the first bit transmission, the data is loaded into the shift register in parallel, then shifted in serial and output to the SD pin (MSB first). See [Supported Audio Protocols](#) for more details on write operations in the various I2S standard modes.

**Receive Sequence**

This working mode is basically the same as the transmit mode, only the transmitting and receiving settings of the I2S\_CTRL register are different, and the RXE bit is set to 1 to allow reception. See [Supported Audio Protocols](#) for more details on read operations in the various I2S standard modes. If new data is received while previously received data has not been read, an overflow error will be generated and the I2S\_ER.RXERR flag will be set to 1. If the I2S\_CTRL.EIE bit is set to 1, an interrupt will be generated to indicate the error.

**33.3.6.2 I2S Slave Mode**

I2S can be configured as follows:

- Transmit slave or receive slave (using I2S half-duplex mode).
- Simultaneous transmit and receive slave (using I2S full-duplex mode).

The rules followed by this working mode are basically the same as the I2S master mode. In slave mode, the I2S interface does not generate a clock. Clock and WS signals are input from an external master device connected to the I2S interface. This way, the user does not need to configure the clock.

**Steps:**

- Step1.** Set the pins that I2S needs to use.

- Step2.** Set the I2S\_CFGR register, select the I2S standard through the I2SSTD and PCMSYNC bits, select the data length through the DATLEN bit and select the number of bits per channel by configuring the CHLEN bit.
- Step3.** If it need to use interrupt, set the interrupt register of the system.
- Step4.** If it need to use DMA, set the relevant register for DMA.
- Step5.** If it want to transmit data, 1-4 data to be sent should be pre-written into I2S\_TXBUF.
- Step6.** Set I2S\_CTRL register, including working mode setting, communication mode setting, clock output permission setting, data output permission setting, FIFO reset setting, transmitting/receiving buffer threshold setting, etc., working mode WMS bit select I2S slave mode.
- Step7.** Set the interrupt permission bit.
- Step8.** Set I2S\_CTRL.TXE and I2S\_CTRL.RXE, and the action starts.

### Transmit Sequence

The transmit sequence begins when WMS is set to 1, TXE is set to 1, and the external master transmits the clock and requests data transfer via the WS signal. When communication starts, data is transferred from the transmit buffer to the shift register. During first bit transmission, data is loaded from the internal bus into the shift register in parallel, then shifted in serial and output to the SD pin (MSB first). Every time the transmit buffer FIFO space is larger than the set threshold, if the I2S\_CTRL.TXIE bit is set to 1, an interrupt will be generated. See [Supported Audio Protocols](#) for more details on write operations in the various I2S standard modes.

In order to ensure continuous audio data transmission, the next data to be transmitted must be written into the TX FIFO before the end of the current data transmission. If the first clock edge of the next data communication arrives when the data has not been written into the TX FIFO, a transmit underflow will occur, the I2S\_ER.TXERR flag will be set to 1 and an interrupt may be generated. If the I2S\_CTRL.EIE bit is set to 1, an interrupt will be generated when the I2S\_ER.TXERR flag becomes 1.

### Receive Sequence

This working mode is basically the same as the transmitting mode, only the transmitting and receiving settings of the I2S\_CTRL register are different, and the RXE bit is set to 1 to allow reception. See [Supported Audio Protocols](#) for more details on read operations in the various I2S standard modes. If new data is received while previously received data has not been read, a receive overflow error will be generated and the RXERR flag will be set to 1. If the I2S\_CTRL.EIE bit is set to 1, an interrupt will be generated to indicate the error.

#### 33.3.7 Interrupt

The interrupt sources of I2S include transmitting buffer active space greater than the alarm threshold, receiving buffer active space less than the alarm threshold, receiving overflow, transmit underflow and transmit overflow. The transmit underflow and transmit overflow are integrated into the I2S transmit error interrupt TXERR, so it is necessary to judge the actual interrupt source through the flag. The specific description of the I2S interrupt sources is shown in the following table. Once the interrupt condition is established, the corresponding interrupt request is generated.

Table 33-4 I2S Interrupt Request

| Interrupt Event                                                             | Event flag | Enable Control Bit |
|-----------------------------------------------------------------------------|------------|--------------------|
| Active space of the transmitting buffer is greater than the alarm threshold | TXBA       | TXIE               |

| Interrupt Event                                                                                     | Event flag | Enable Control Bit |
|-----------------------------------------------------------------------------------------------------|------------|--------------------|
| Active space of the receiving buffer is less than the alarm threshold                               | RXBA       | RXIE               |
| Receiving data area is full and there is still a request to write data, and the receiving overflows | RXERR      | EIE                |
| Transmitting data area is empty and there are still transmitting requests, transmitting underflow   | TXERR      | EIE                |
| Transmitting data area is full and there is still a request to write data, transmitting overflow    | TXERR      | EIE                |

Users can write the vector corresponding to the event trigger source into different trigger object registers to implement various event trigger functions. For the vectors corresponding to the above event trigger sources, please refer to the "Interrupt Event List" of "Interrupt Controller (INTC) " chapter.

## 33.4 Register Description

### 33.4.1 Register List

- I2S1 base address: 0x4001E000
- I2S2 base address: 0x4001E400
- I2S3 base address: 0x40022000
- I2S4 base address: 0x40022400

Table 33-5 Inter\_IC Sound Bus (I2S) Register Offset

| Offset | Register  | Description                            | Width |
|--------|-----------|----------------------------------------|-------|
| 0x000  | I2S_CTRL  | I2S Control Register                   | 32    |
| 0x004  | I2S_SR    | I2S Status Register                    | 32    |
| 0x008  | I2S_ER    | I2S Error Status Register              | 32    |

| 1    | RXBA     | Receive buffer alarm (related to water level)  | <ul style="list-style-type: none"> <li>0b0: Receive buffer without alarm</li> <li>0b1: Receive buffer alarm</li> </ul>   | RO     |
| 0    | TXBA     | Transmit buffer alarm (related to water level) | <ul style="list-style-type: none"> <li>0b0: Transmit buffer without alarm</li> <li>0b1: Transmit buffer alarm</li> </ul> | RO     |

**Note**

In addition to FIFO and shift register, there are two buffer units inside I2S. The FIFO flag only indicates the data status in the FIFO, not all the stored data in the I2S.

## 33.4.4 I2S Error Status Register (I2S\_ER)

## 33.5 Precautions

### 33.5.1 Precautions when Using as a Master

1. When I2S acts as the master to transmit data only, if all the data in I2S\_TXBUF has been transmitted and no new data is written, I2S will pause the action after the last data is transmitted, and I2S will no longer generate communication clock at this time, the transmit error flag bit TXERR will be set to 1. At this time, the user can choose to write the I2S\_CTRL.TXE bit as 0 to close the I2S, or write new transmitting data to I2S\_TXBUF to continue transmitting. When continuing to transmit, WS will restart from the left channel (Philips, MSB/LSB mode).

If the I2S\_CTRL.TXE bit is directly written as 0 during the transmitting action, the I2S will be turned off immediately, and the current data transmitting will be terminated. This approach will lead to the inability to grasp the state of the slave, and the slave will receive data confusion when restarting communication without resetting the slave. Therefore, it is recommended that the user write the I2S\_CTRL.TXE bit to 0 to close the I2S when the I2S is in the paused state.

2. When I2S is used as the master to only receive data, if you want to temporarily stop the receiving action, it can write two frames of dummy data in advance, and set I2S\_CTRL.TXE to 1 when it need to pause and count to the corresponding position. When the baud rate is 8kHz-96kHz, advance 4 pieces of data TXE are set to 1, and when the baud rate is 192kHz, 5 pieces of data TXE are set to 1 in advance. After the two frames of dummy data are transmitted, I2S will pause. At this time, I2S will no longer generate a communication clock, and the transmission error flag TXERR will be is set to 1. At this time, the user can choose to clear I2S\_CTRL.TXE and I2S\_CTRL.RXE to close I2S, or write another frame of dummy data to I2S\_TXBUF to restart the communication action, and turn off TXE when restarting to receive the first data after the pause, and WS will restart from the left channel when restart the action (Philips, MSB/LSB mode). When the communication clock is regenerated, clear I2S\_CTRL.TXE to return to the receive-only state. Please refer to the figure below for details.

Figure 33-16 Master only Receives and Temporarily Stops Receiving

If the I2S\_CTRL.RXE bit is directly written to 0 during the receiving action; the I2S will be turned off immediately, and the current data reception will be terminated. This approach will lead to the inability to grasp the status of the slave. When communication is restarted without resetting the slave, it causes confusion in the data transmitted by the slave. Therefore, it is recommended that the user clear the I2S\_CTRL.TXE and I2S\_CTRL.RXE bits when the I2S is in a paused state to disable I2S.

3. When I2S acts as the master in full-duplex operation, if all the data in I2S\_TXBUF has been transmitted and no new data is written, I2S will suspend the action after the last data is transmitted, and I2S

will no longer generate the communication clock; the transmit error flag bit TXERR will be set to 1. At this time, the user can choose to clear I2S\_CTRL.TXE and I2S\_CTRL.RXE to close I2S, or write new transmitting data to I2S\_TXBUF to continue transmitting and receiving operations. When continuing to transmit, WS will restart from the left channel (Philips, MSB/LSB mode).

If the I2S\_CTRL.TXE and I2S\_CTRL.RXE bits are directly written as 0 during full-duplex operation; the I2S will be turned off immediately, and the current data transmission and reception will be terminated. This approach will lead to the inability to grasp the status of the slave, and the communication data will be confused when restarting the communication without resetting the slave. Therefore, it is recommended that the user clear the I2S\_CTRL.TXE and I2S\_CTRL.RXE bits to close I2S when the I2S is in the paused state.

4. When I2S is used as the master to transmit PCM short frame data, when I2S is suspended because I2S\_TXBUF has no new data writing action, there are two setting methods to restart the transmission, which method to choose depends on the data reception specification of the slave to determine. If the slave needs to detect the status of WS every time it receives data, then after I2S pauses, you need to set I2S\_CTRL.TXE to 0 first, then write new send data to I2S\_TXBUF and then set I2S\_CTRL.TXE to 1 to restart the transmission. The specific actions are shown in the figure below.

Figure 33-17 PCM Short Frame Master Resends After Suspension of Transmission Method 1

If the slave only detects the WS state when receiving the first frame of data, after the I2S pauses, it can directly write new transmitting data to I2S\_TXBUF to restart the transmission. The specific actions are shown in the figure below.

Figure 33-18 PCM Short Frame Master Resends After Suspension of Transmission Method 2

### 33.5.2 Precautions when Using as a Slave

1. When I2S acts as a slave, it is necessary to ensure that after all register configurations are completed, set I2S\_CTRL.TXE or I2S\_CTRL.RXE to start the slave operation.
2. When I2S starts the slave operation in Philips, MSB/LSB mode, it is necessary to ensure that the WS signal is at the right channel level state when starting. When I2S starts the slave operation in PCM mode, it is necessary to ensure that the WS signal is low level status when starting.
3. When the I2S receives data as a slave, the data received each time can only be read after the start of the next frame of data reception. Therefore, when the communication is paused or terminated, the last frame of data received by the I2S can only be read when the next communication begins.
4. When I2S performs data reception as a slave in Philips, MSB/LSB mode, it will check whether WS is the left channel level when receiving each frame of left channel data. When I2S is receiving data as a slave in PCM mode, before each frame of data is received, it will check whether WS has generated a active level according to the standard communication protocol.
5. When I2S is acting as a slave in full-duplex mode, if all data in I2S\_TXBUF has been transmitted and no new data has been written, the internal transceiver circuit of I2S will suspend operation (i.e., it will not be able to receive data) after the last data is sent, and the transmit error flag TXERR will be set to 1. At this time, the user can choose to use I2S\_CTRL.TXE and I2S\_CTRL.RXE to disable I2S, reset FIFO and set SRST for soft reset, then clear the error flag, and finally enable I2S to transmit and receive new data.

### 33.5.3 Anti-interference Support Function

1. In slave mode, when the received WS signal indication is inconsistent with the configured data channel length, data of each data channel starts to be received according to the WS signal indication to avoid accumulated errors caused by transmission interference.
2. Due to transmission interference, when the WS signal is less than 7 data channel lengths, packet loss may occur.

### 33.5.4 Data Channel Identification Function

1. In Philips/MSB/LSB slave mode, if you need to know whether the received data belongs to the left or right channel, you can first read I2S\_SR.RXID to get the data channel identifier, and then read the I2S\_RXBUF register to get the channel data.
2. Each read of the I2S\_RXBUF register automatically updates the I2S\_SR.RXID at the same time.

### 33.5.5 Four-way Synchronous Control Function

The process of using the four-way synchronization function is as follows:

- Step1.** Disable the clock and disable I2S through the I2S\_CTRL.I2SPLLSEL, I2S\_CTRL.TXE and I2S\_CTRL.RXE bits corresponding to the four-way I2S.
- Step2.** Make the configuration of the four-way I2S consistent and keep I2S\_CTRL.I2SPLLSEL, I2S\_CTRL.TXE and I2S\_CTRL.RXE closed.
- Step3.** Set I2S\_CTRL.SYNCSEL of I2S1.
- Step4.** Enable the clocks of the four-way I2S through I2S\_CTRL.I2SPLLSEL of I2S1.
- Step5.** Enable the TX and RX of four-way I2S through I2S\_CTRL.TXE and I2S\_CTRL.RXE of I2S1.
- Step6.** Read and write the buffer FIFO data registers corresponding to the four-way I2S to transmit and receive data.

**Note**

Only the selection of the internal clock (I2SPLL) through I2S\_CTRL.CLKSEL is supported.

### 33.5.6 Other Precautions

1. Recommended FIFO clearing process:
  - Disable I2S by I2S\_CTRL.TXE and I2S\_CTRL.RXE;
  - Reset FIFO by I2S\_CTRL.FIFOR;
  - Soft reset via I2S\_CTRL.SRST.
2. Recommended ERR clearing process:
  - Disable I2S by I2S\_CTRL.TXE and I2S\_CTRL.RXE;
  - Reset FIFO by I2S\_CTRL.FIFOR;
  - Soft reset via I2S\_CTRL.SRST;
  - Clear the ERR flag.
3. Description of each reset bit in the control register:
  - The I2S\_CTRL.SRST bit is used to reset the working circuit and clear the internal shift register, and will not affect the register configuration;
  - The I2S\_CTRL.FIFOR bit is used to reset the FIFO and will not affect other circuits and registers.
4. In addition to the shift register, the RX/TX circuit also has two caches that will obtain data from the RX/TX FIFO according to the situation. The cache is cleared via FIFOR.

## 34 USB2.0 High-Speed Module (USBHS)

### 34.1 Introduction

The USB High-Speed (USBHS) controller offers a range of USB communication solutions for portable devices. The USBHS controller supports both host mode and device mode. The chip integrates a full-speed PHY internally and supports an external high-speed PHY via the ULPI interface. In host mode, the USBHS controller supports high-speed (HS, 480 Mbit/s), full-speed (FS, 12 Mbit/s), and low-speed (LS, 1.5 Mbit/s) transceivers, while in device mode, it supports only high-speed (HS, 480 Mbit/s) and full-speed (FS, 12 Mbit/s) transceivers. The USBHS controller supports all four types of transfers defined by the USB 2.0 protocol (Control transfer, Bulk transfer, Interrupt transfer, and Isochronous transfer). The USBHS controller supports the LPM (Link Power Management) function.

The chip integrates a full-speed PHY that supports only full-speed (FS, 12 Mbit/s) and low-speed (LS, 1.5 Mbit/s) transfers. By connecting an external high-speed PHY via the ULPI interface, it supports high-speed (HS, 480 Mbit/s), full-speed (FS, 12 Mbit/s), and low-speed (LS, 1.5 Mbit/s) transfers.

The protocol followed is as follows:

- Universal Serial Bus Revision 2.0 Specification
- USB 2.0 Link Power Management Addendum Engineering Change Notice to the USB 2.0 specification, July 16, 2007
- Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007

### 34.2 Features

#### 34.2.1 General Features

- Supports two PHY interfaces
  - ▶ Built-in on-chip USB 2.0 full-speed PHY (needs to set USB\_SYCTLREG.USBHS\_FSPHYE=1 to enable).
  - ▶ ULPI interface for connecting an external high-speed PHY.
- Support host mode and device mode
- Supports HS/FS SOF and low-speed "Keep-alive" tokens with the following functions:
  - ▶ SOF pulse pin output function
  - ▶ The SOF pulse can serve as an internal event source to trigger operations of modules such as TIMER and DMA.
  - ▶ Configurable frame period
  - ▶ Configurable frame end interrupt
- The module embeds DMA and supports software-configurable AHB burst transmission types
- Supports power-saving functions, such as USB suspend, stopping RAM clock, and stopping PHY domain clock
- Equipped with a dedicated 8KB RAM featuring advanced FIFO control
  - ▶ The RAM space can be partitioned into different FIFOs for flexible and efficient utilization of RAM
  - ▶ Each FIFO can store multiple data packets
  - ▶ Dynamic allocation of memory area
  - ▶ The FIFO size can be configured to non-power-of-two values for continuous memory unit utilization
- Within one frame, no application intervention is required to achieve maximum USB bandwidth

- The mode (Host Mode or Device Mode) can be automatically determined based on the ID line level

### 34.2.2 Host Mode Features

- Host mode supports USB2.0 high-speed (HS, 480Mbit/s), full-speed (FS, 12Mbit/s), and low-speed (LS, 1.5Mbit/s) transmissions
- The VBUS voltage needs to be generated by an external power supply chip
- Up to 16 host channels (Pipes) : Each channel can be dynamically reconfigured to support any type of USB transfer
- Built-in hardware scheduler capable of:
  - ▶ Store up to 8 interrupt plus isochronous transfer requests in a periodic hardware queue
  - ▶ Store up to 8 control and bulk transfer requests in a non-periodic hardware queue
- Manages a shared RX FIFO, a periodic TX FIFO, and a non-periodic TX FIFO to efficiently utilize USB data RAM

### 34.2.3 Device Mode Features

- Slave mode supports USB2.0 high-speed (HS, 480Mbit/s) and full-speed (FS, 12Mbit/s) transmission
- 1 bidirectional control endpoint 0
- 15 OUT endpoints, configurable to support bulk transfer, interrupt transfer, or isochronous transfer.
- 15 IN endpoints, configurable to support bulk transfer, interrupt transfer, or isochronous transfer.
- Contains 16 transmit FIFOs (one for each IN endpoint) and one receive FIFO (shared by all OUT endpoints)
- Supports remote wake-up function
- Supports soft disconnect function
- The VBUS PIN supports 5V withstand voltage

## 34.3 Functional Description

### 34.3.1 System Block Diagram

Figure 34-1 USBHS System Block Diagram

### 34.3.2 Pin Description

Table 34-1 USBHS Pin Description

| Pin Name       | Direction    | Applicable Mode | Corresponding Pins | Function Description              | Applicable PHY                     |
|----------------|--------------|-----------------|--------------------|-----------------------------------|------------------------------------|
| USBHS_VBUS     | Input        | Equipment       | PB13               | Power port, 5V with-stand voltage | On-chip full-speed PHY             |
| USBHS_DP       | Input/Output | Host, de-vice   | PB15               | Differential data D+              | On-chip full-speed PHY             |
| USBHS_DM       | Input/Output | Host, de-vice   | PB14               | Differential data D-              | On-chip full-speed PHY             |
| USBHS_DRVVBUS  | Output       | Host            | PD8                | External power chip enable        | On-chip full-speed PHY             |
| USBHS_ID       | Input        | Host            | PB12               | USB A-B device identification     | On-chip full-speed PHY             |
| USBHS_SOF      | Output       | Host, de-vice   | PA4                | SOF output pulse                  | On-chip full-speed PHY<br>ULPI PHY |
| USBHS_ULPI_CLK | Input        | Host, de-vice   | PE12, PA5          | ULPI Clock                        | ULPI PHY                           |
| USBHS_ULPI_DIR | Input        | Host, de-vice   | PC2, PI11          | ULPI Direction                    | ULPI PHY                           |

| Pin Name       | Direction    | Applicable Mode | Corresponding Pins | Function Description | Applicable PHY |
|----------------|--------------|-----------------|--------------------|----------------------|----------------|
| USBHS_ULPI_NXT | Input        | Host, device    | PC3, PH4           | ULPI Next            | ULPI PHY       |
| USBHS_ULPI_STP | Output       | Host, device    | PC0                | ULPI Stop            | ULPI PHY       |
| USBHS_ULPI_D0  | Input/Output | Host, device    | PE13, PA3          | ULPI Data 0          | ULPI PHY       |
| USBHS_ULPI_D1  | Input/Output | Host, device    | PE14, PB0          | ULPI Data 1          | ULPI PHY       |
| USBHS_ULPI_D2  | Input/Output | Host, device    | PE15, PB1          | ULPI Data 2          | ULPI PHY       |
| USBHS_ULPI_D3  | Input/Output | Host, device    | PB10               | ULPI Data 3          | ULPI PHY       |
| USBHS_ULPI_D4  | Input/Output | Host, device    | PB11, PD9          | ULPI Data 4          | ULPI PHY       |
| USBHS_ULPI_D5  | Input/Output | Host, device    | PB12               | ULPI Data 5          | ULPI PHY       |
| USBHS_ULPI_D6  | Input/Output | Host, device    | PB13               | ULPI Data 6          | ULPI PHY       |
| USBHS_ULPI_D7  | Input/Output | Host, device    | PB5, PE11          | ULPI Data 7          | ULPI PHY       |

Since the USBHS\_DP and USBHS\_DM pins are multiplexed with universal GPIO, it is recommended to disable the digital function of the corresponding pins when using the USBHS on-chip full-speed PHY. The USBHS\_DP and USBHS\_DM functions are analog functions, independent of the associated PFSR register settings. For details, see the relevant description in the "General-Purpose I/O (GPIO) " chapter. In addition, when the USBHS function is not used, the digital function pin corresponding to the USBHS\_DP and USBHS\_DM pins consumes additional current when flipped.

### 34.3.3 Clock and Work Mode

The clocks used by USBHS are as follows:

- For a 48MHz clock. The internal PLL circuit generates this 48MHz clock. The PLL clock source must select the external high-speed oscillator. Before using the USBHS module, the USBHS clock must be properly configured in the CMU module.
- For a 60MHz clock, use the UPLI interface to connect to the input clock of the high-speed PHY. It is used only when the external PHY is connected.
- The module clock PCLK1 needs to be configured in the CMU module, and the clock must be greater than or equal to 60MHz.

USBHS can operate as either a host or device, and includes an on-chip full-speed PHY and a ULPI interface for an external high-speed PHY.

The pull-up and pull-down resistors are integrated inside the on-chip full-speed PHY, and USBHS can automatically select them based on the current mode and connection status.

When USBHS uses the on-chip full-speed PHY, the VCC voltage range is 3.0-3.63V.

### 34.3.4 Mode Decision

USBHS determines the current operating mode using the following two methods:

- Method 1: Automatic identification based on the status of the USBHS\_ID line. When the USBHS\_ID line is detected at high level, the module works in the device mode. When the USBHS\_ID line is detected at low level, the module works in host status.
- Method 2: Force host/device mode. By setting the FDMOD or FHMOD bit in the USBHS\_GUSBCFG register to 1, the module will ignore the USBHS\_ID line level and forcibly worked in device or host mode.

### 34.3.5 Host Function

#### Function Introduction

When USBHS works in host mode, VBUS is the 5V power supply pin specified by the USB protocol. The internal PHY does not support 5V power supply, so an external USB power chip is required to power the device. USBHS\_DRVVBUS is used to enable the external USB power chip. The overcurrent detection of the external power supply chip can be implemented through the external interrupt IRQ of this MCU. In host mode, USBHS\_VBUS can be used as GPIO.

A typical USB host mode system architecture diagram is as follows:

Figure 34-2 USBHS host Mode System Architecture Diagram

#### Host Port Power Supply

This MCU cannot output 5V to supply VBUS. To achieve this, a USB power chip or a basic power switch (if the circuit board provides 5V power) must be added externally to the microcontroller to drive the 5V VBUS line. The external power chip can be driven by any GPIO output or USBHS\_DRVVBUS. When the application determines to use GPIO to control an external device for providing VBUS, the port power bit (USBHS\_HPRT.PWPR) in the host port control and status register must still be set to 1.

#### Host Detects Device Connection and Disconnection

The USB device will be detected immediately after connection. The USBHS module will issue a host port interrupt signal, which is triggered by the device connection bit (USBHS\_HPRT.PCDET) in the host port control and status register.

A device disconnect event will trigger a disconnect detection interrupt (USBHS\_GINTSTS.DISCINT).

## Host Enumeration

After a device connection is detected, if a new device is connected, the host must initiate the enumeration process by sending a USB reset and configuration command to the new device.

The application sets the port reset bit (USBHS\_HPRT.PRST) in the host port control and status register to 1, maintaining this state for a minimum of 10ms and a maximum of 20ms, thereby driving the USB reset signal (single-ended zero) through the USB driver. The application calculates the duration of this process, then clears the port reset bit.

After the USB reset sequence is completed, the port enable/disable change bit (USBHS\_HPRT.PENCHNG) triggers a host port interrupt immediately, notifying the application that the enumerated device speed can be read from the port speed field (PSPD in USBHS\_HPRT) in the host port control and status register, and that the host has started driving SOF (HS/FS) or Keep-alive tokens (LS). At this point the host is ready to enumerate the device by sending commands to the device.

## Host Suspend

The application suspends the USB bus by setting the port suspend bit (PSUSP in USBHS\_HPRT) in the host port control and status register to 1. The USBHS module stops sending SOF and enters suspend status.

The bus can exit suspend status through autonomous activity (remote wake-up) from a remote device. In this scenario, the remote wake-up signal will trigger a remote wake-up interrupt (USBHS\_GINTSTS.WKUPINT). The hardware automatically resets the port resume bit (USBHS\_HPRT.PRES) in the host port control and status register and drives the resume signal via USB autonomously. The application must time the resume window, then clear the port resume bit to exit the suspend status and restart SOF.

If the host initiates exit from suspend status, the application must set the port resume bit to 1 to activate the resume signaling on the host port, time the resume window, and finally clear the port resume bit.

## Host Channel

The USBHS module implements 16 host channels. Each host channel can be used for USB host transfers (USB pipes). The host can handle up to 8 transfer requests at the same time. If the application has more than 8 transfer requests pending, the host controller driver (HCD) must reassign the channel for unprocessed transfer requests after the channel is released from the previous task (i.e., upon receiving the transmission complete and channel halt interrupts).

Each host channel can be configured to support input/output and periodic/non-periodic transactions. Each host channel uses dedicated control (HCCHARx) register, transfer configuration (HCTSIZx) register/interrupt (HCINTx) register, and its associated interrupt mask register (HCINTMSKx).

### Host Channel Control

The application can control the host channel through the host channel x characteristic register (HCCHARx) with the following settings:

- Channel enabled/disabled
- Set the target USB device speed: HS/FS/LS
- Set the target USB device address
- Set the endpoint number on the target USB device for communication with this channel
- Sets the transfer direction on this channel: IN/OUT

- Set the type of USB transfer on this channel: control/bulk/interrupt/isochronous
- Set the maximum packet length of the device endpoint for communication with this channel
- Set the frame for periodic transfer: odd frame/even frame

### Host Channel Transfer

The host channel transfer size register (HCTSIZx) allows applications to program the transmission size parameter and read the transfer status. The settings for this register must be completed before setting the channel enable bit to 1 in the host channel characteristics register. After enabling the endpoint, the packet count field immediately becomes read-only, while the USBHS module updates this field based on the current transmission status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- The number of packets that make up the entire transfer size
- Initial data PID

### Host Channel Status/Interrupt

Host channel x interrupt register (HCINTx) indicates the endpoint status upon occurrence of USB and AHB related events. When the host channel interrupt bit (USBHS\_GINTSTS.HCINT) in the interrupt register is set to 1, the application must read these registers to obtain detailed information. Before reading these registers, the application must first read the host all channels interrupt (HCAINT) register to obtain the channel number of the host channel-x interrupt register. The application must clear the corresponding bit in this register to clear the corresponding bits in the HCAINT and GINTSTS registers. The USBHS\_HCINTMSKx register also provides mask bits for each interrupt source on every channel.

The host module provides the following status check and interrupt generation functions:

- Transfer complete interrupt, indicating both the application (AHB) and USB side have completed data transfer
- The channel stops due to transmission completion, USB transaction error, or a disable command issued by the application
- The associated transmit FIFO is half-empty or in full empty status (IN endpoint)
- ACK response received
- NAK response received
- STALL response received
- USB transaction error due to CRC check failure, timeout, bit stuffing error, or incorrect EOP
- Crosstalk error
- Frame overflow
- Error in toggling bit for data synchronization

## 34.3.6 Device Function

### Function Introduction

When the USBHS in device mode, VBUS is the 5V power supply pin specified by the USB protocol and is a 5V withstand voltage pin. This module continuously monitors the VBUS line level status to connect or disconnect devices. The USBHS\_VBUS port must be connected to the VBUS power supply through a resistor of at least 1kΩ.

A typical USB device mode system block architecture diagram is as follows:

Figure 34-3 USBHS Device Mode System Architecture Diagram

### Power Supply State of Device

When the module detects that USBHS\_VBUS is at a high level, it enables the USB device to enter the power supply state. Then, USBHS automatically connects the DP pull-up resistor, signals a full-speed device connection to the host, and generates a session request interrupt (USBHS\_GINTSTS.VBUSINT), indicating entry into the powered state.

In addition, the USBHS\_VBUS input ensures the host provides a active VBUS level during USB operation. If a low level is detected on VBUS (e.g., caused by power supply interference or host port shutdown), USBHS will automatically disconnect.

Under power supply, the USBHS expects to receive a reset signal from the host. Other USB operations cannot be performed. Upon receiving the reset signal, a reset interrupt is immediately generated (USBHS\_GINTSTS.USB\_RST). After the reset signal ends, an enumeration complete interrupt (USBHS\_GINTSTS.ENUMDNE) will be generated, and USBHS will then enter the default state.

### Device Default State

By default, USBHS expects to receive a SET\_ADDRESS command from the host. Other USB operations cannot be performed. When a active SET\_ADDRESS command is decoded on USB, the application writes the corresponding address value to the device address field (USBHS\_DCFG.DAD) in the device configuration register. The USBH immediately enters the address state and is ready to respond to host transactions using the configured USB address.

### Device Suspend State

The USBHS device continuously monitors USB activity. After the USB idle time reaches 3ms, an early suspend interrupt (USBHS\_GINTSTS.ESUSP) will be issued, and after 3ms, the suspend interrupt (USBHS\_GINTSTS.USBSUSP) will confirm the device enters suspend status. Then, the device suspend bit (USBHS\_DSTS.SUSPSTS) in the devices status register is automatically set to 1, and USBHS immediately enters the suspend status.

The device can exit the suspend status by itself. In this case, the application will set the remote wake-up signal bit (USBHS\_DCTL.RWUSIG) in the device control register to 1 and clear it within 1ms to 15ms.

However, if the device detects a resume signal from the host, it will generate a resume interrupt (USBHS\_GINTSTS.WKUPINT), and the device suspend bit will be automatically cleared.

### Device Soft-off

The power supply state can be exited via software using the soft disconnect function. Setting the soft disconnect bit (USBHS\_DCTL.SDIS) in the device control register to 1 removes the DP pull-up resistor. At

this point, even though the USB cable is not physically unplugged from the host port, the host will still detect a device disconnect and trigger an interrupt.

## Device Endpoint

### Endpoint Type

The USBHS module implements the following USB endpoints:

- Control endpoint 0:
  - ▶ Bidirectional and handles only control messages
  - ▶ Use a separate set of registers to handle IN and OUT transactions
  - ▶ Dedicated control (USBHS\_DIEPCTL0/USBHS\_DOEPCTL0) register, transfer configuration (USBHS\_DIEPTSIZ0/USBHS\_DOEPSIZ0) register, and status interrupt (USBHS\_DIEPINTx/USBHS\_DOEPINT0) register. The available bit groups in the control and transmission size registers differ slightly from those in other endpoints
- 15 IN endpoints:
  - ▶ Each endpoint can be configured to support isochronous, bulk, or interrupt transfer types.
  - ▶ Each endpoint has dedicated control (USBHS\_DIEPCTLx) register, transfer configuration (USBHS\_DIEPTSIZx) register, and status interrupt (USBHS\_DIEPINTx) register
  - ▶ The device IN endpoint universal interrupt mask register (USBHS\_DIEPMSK) can be used to enable/disable the same type of interrupt sources on all IN endpoints (including EP0).
  - ▶ Supports interrupt for incomplete isochronous IN transfer (USBHS\_GINTSTS.IISOIXFR). This interrupt is triggered when at least one isochronous IN endpoint has an incomplete transfer in the current frame. This interrupt is triggered together with the periodic frame interrupt (USBHS\_GINTSTS/EOPF)
- 15 OUT endpoints:
  - ▶ Each endpoint can be configured to support isochronous, bulk, or interrupt transfer types.
  - ▶ Each endpoint has dedicated control (USBHS\_DOEPCTLx) register, transfer configuration (USBHS\_DOEPSIZx) register, and status interrupt (USBHS\_DOEPINTx) register.
  - ▶ The device OUT endpoint universal interrupt mask register (USBHS\_DOEPMSK) can be used to enable/disable the same type of interrupt sources on all OUT endpoints (including EP0).
  - ▶ Supports for incomplete isochronous OUT transfer interrupts (USBHS\_GINTSTS.INCOMPISOOUT), which will trigger when at least one transfer on an isochronous OUT endpoint is incomplete in the current frame. This interrupt is triggered together with the periodic frame interrupt (USBHS\_GINTSTS/EOPF).

### Endpoint Control

Applications can control the endpoint through the device endpoint x IN/OUT control register (DIEPCTLx/DOEPCTLx) with the following operations:

- Endpoint enable/disable
- Enable endpoint in current configuration
- Set USB transfer type (Isochronous, Bulk, and Interrupt)
- Supported packet size setting
- Set the Tx-FIFO number associated with the IN endpoint
- Configure the desired data0/data1 PID for receiving or transmitting (applicable only to bulk/interrupt transfers)
- Set the corresponding odd/even frame for receive or transmit transactions (isochronous transfer only)

- The NAK Bit can be set to reply NAK to the host request regardless of the current FIFO status
- The STALL bit can be set to make the hardware respond with STALL to all host tokens for this endpoint
- The OUT endpoint can be configured in listen mode, where CRC checking is disabled for received data

### Endpoint Transfer

The device endpoint x transmission size register (DIEPTSIZE<sub>x</sub>/DOEPTSIZE<sub>x</sub>) allows the application to program transfer size parameters and read transfer status. The setting of this register must be completed before setting the endpoint enable bit in the endpoint control register to 1. After enabling the endpoint, these fields immediately become read-only, while the USBHS block updates them based on the current transmission status.

The following transfer parameters can be programmed:

- Transfer size in bytes
- The number of packets that make up the entire transfer

### Endpoint Status/Status

Device endpoint x interrupt register (DIEPINT<sub>x</sub>/DOEPINT<sub>x</sub>) indicates the endpoint status upon occurrence of USB and AHB related events. When the OUT endpoint interrupt bit or IN endpoint interrupt bit (corresponding to the USBHS\_GINTSTS.OEPINT/IEPINT bit) in the module interrupt register is set to 1, the application must read these registers to obtain detailed information. Before an application can read these registers, it must first read the device overall endpoint interrupt (USBHS\_DAINTE) register to obtain the endpoint number of the device endpoint x interrupt register. The application must clear the corresponding bit in this register to clear the corresponding bits in the DAINTE and GINTSTS registers.

The module provides the following status check and interrupt generation functions:

- Transfer complete interrupt, indicating to the application that both the AHB and the USB side have completed the data transfer
- Setup phase completed (only for OUT endpoints of control transfer type)
- The associated transmit FIFO is half-empty or in full-empty status (IN endpoint)
- A NAK reply has been sent to the host (IN endpoint for isochronous transfers only)
- IN token received while TxFIFO is empty (only for IN endpoints of bulk and interrupt transfer types)
- Received OUT token when endpoint is not enabled
- Babble error detected
- Application closes endpoint enable
- The application sets NAK to take effect for the endpoint (only applicable to IN endpoints of isochronous transfer type)
- Received more than 3 consecutive setup packets (only applicable to control-type OUT endpoints)
- Timeout detected (only for IN endpoints of control transfer type)

### 34.3.7 SOF Pulse Pin Output Function

In both host and device modes, USBHS can monitor, track, and configure SOF frames, and also features SOF pulse output functionality. The SOF pulse is output through the USBHS\_SOF pin, with a pulse width of 16 HCLK clock periods.

#### Host SOF

In host mode, the number of PHY clocks occurring between two consecutive SOF (HS/FS) or keep-alive (LS) tokens can be programmed in the host frame interval register (HFIR), allowing the application to control the SOF frame period. An interrupt is generated at the start of frame (SOF bit in

USBHS\_GINTSTS). The current frame number and the remaining time until the next SOF can be tracked by the application in the host frame number register (HFNUM).

Using the SOFEN bit in the USBHS system control register USBHS\_SYCTLREG), a SOF pulse signal with a width of 16 HCLK system clock periods can be output from the USBHS\_SOF pin simultaneously with any issued SOF token.

In addition, the SOF pulse can also serve as an internal event to trigger operations of external modules such as DMA transfers and TIMER counting.

### Device SOF

In device mode, each time the USB receives a SOF token, it will trigger a start-of-frame interrupt (SOF bit in USBHS\_GINTSTS). The corresponding frame number can be read from the device status register (FNSOF bit in USBHS\_DSTS). Using the SOFEN bit in the USBHS system control register USBHS\_SYCTLREG, a 16 HCLK system clock period SOF pulse signal can be generated and output on the USBFS\_SOF pin for external availability.

In addition, the SOF pulse can also work as an internal event to trigger operations of external modules such as DMA transfers and TIMER counting.

The periodic frame end interrupt (GINTSTS/EOPF) is used to notify the application when 80%, 85%, 90%, or 95% of the frame interval time has elapsed, depending on the periodic frame interval field in the device configuration register (PFIVL bit in the USBHS\_DCFG). This function can be used to determine whether all isochronous communications for this frame are completed.

### 34.3.8 Power Consumption Control

When the USBHS module is not used, the HCLK and PHY clocks of the USBHS module can be stopped through the CMU module to reduce power consumption.

When using the USB module, if the device USB session has not started or the device is not connected, power reduction techniques can be employed in the suspend status.

- Stop PHY clock (STPPCLK bit in USBHS\_GCCTL)

When the stop PHY clock bit in the clock gating control register is set to 1, most 48MHz internal clock domains in the USBHS full-speed module are gated off by clock gating. Even if the application still provides a clock input, the dynamic power consumption caused by clock signal toggling in the block will be saved. Additionally, most units of the transceiver will be turned off, with only the portion responsible for detecting asynchronous recovery events or remote wake-up events remaining active.

- HCLK gating (GATEHCLK bit in USBHS\_GCCTL)

When the GATEHCLK bit in the clock gating control register is set to 1, most HCLK system clock domains inside the USBHS module are gated off by clock gating. Only the register read and write interface remains active. Even when the application still provides a clock input, the dynamic power consumption caused by clock signal toggling in the block is saved.

To save dynamic power consumption, the clock is only provided to the USB data FIFO when it is accessed by the USBHS module.

### 34.3.9 Dynamic Update of USBHS\_HFIR Register

In host mode, the USB module has the function to dynamically fine-tune the frame period, enabling synchronization between the external device and the SOF frame. If the USBHS\_HFIR register is modified within the current SOF frame, the SOF period will be adjusted accordingly in the next frame. For detailed specifications, refer to the figure below.

Figure 34-4 Schematic Diagram of USBHS Dynamic Update for USBHS\_HFIR Register

34.3.10 Data FIFO

The USBHS system features 8KB of dedicated RAM and employs an efficient FIFO control mechanism. In the USBHS module, the packet FIFO controller divides the RAM space into multiple TxFIFOs (Before USB transfer, the application pushes data into it for temporary storage) and a single RxFIFO (The data received from the USB is briefly stored in it before being read by the application).

The number and organization of FIFOs built in RAM depend on the device's role. In device mode, a TxFIFO is configured for each active IN endpoint. The FIFO size is software-configurable to better meet application requirements.

34.3.11 Host FIFO Architecture

Figure 34-5 FIFO Architecture Diagram in Host Mode

Host RxFIFO

The host uses a receive FIFO to handle all periodic and non-periodic transactions. The FIFO serves as a receive buffer to store data received from USB (the data portion of received packets) until it is transferred to system memory. As long as there is space in the FIFO, data packets from the device's IN endpoint are received and stored sequentially. The status of each received data packet (including the host target channel, byte count, data PID, and checksum of the received data) is also stored in the FIFO. The size of the receive FIFO is configured in the receive FIFO size register (GRXFSIZ).

The single receive FIFO architecture enables the USB host to efficiently fill the receive data buffer:

- All IN configuration host channels share the same RAM buffer (shared FIFO)

- For any sequence of IN tokens driven by host software, the USBHS module can fill the receive FIFO up to its limit.

The application receives an RxFIFO non-empty interrupt whenever at least one data packet is available for reading in the RxFIFO. The application reads packet information from the receiving status and out-stack register and finally retrieves the data from the RxFIFO.

### Host TxFIFO

The host uses one transmit FIFO for all non-periodic (control and bulk) OUT transactions and the other transmit FIFO for all periodic (isochronous and interrupt) OUT transactions. FIFO serves as a transmit buffer to store data (transmit packets) for USB transmission. The periodic (non-periodic) TxFIFO size is configured in the host periodic (non-periodic) transmit FIFO size (HPTXFSIZ/HNPTXFSIZ) register.

The two TxFIFOs operate based on priority, with periodic communication having higher priority. Therefore, within one USB frame, periodic communication is processed first. At the start of the frame, the built-in host scheduler first processes the periodic request queue, then handles the non-periodic request queue.

The dual transmit FIFO architecture enables the USB host to separately optimize the management of periodic and non-periodic transmit data buffers:

- All host channels configured to support periodic (non-periodic) OUT transactions share the same RAM buffer (shared FIFO).
- For any sequence of OUT tokens driven by host software, the USBHS module can fill the periodic (non-periodic) transmit FIFO up to the limit.

The USBHS module issues a periodic TxFIFO empty interrupt (USBHS\_GINTSTS.PTXFE) whenever the periodic TxFIFO is half-empty or full-empty, depending on the value of the periodic Tx-FIFO empty level bit (USBHS\_GAHBCFG.PTXFELVL) in the AHB configuration register. As long as there is free space in both the periodic TxFIFO and the periodic request queue, the application can pre-write transmit data. The available space can be determined by reading the host periodic transmit FIFO and queue status register (HPTXSTS).

Whenever the non-periodic TxFIFO is half-empty or full-empty, the USBHS module generates a non-periodic TxFIFO empty interrupt (USBHS\_GINTSTS.NPTXFE), depending on the non-periodic TxFIFO empty level bit (USBHS\_GAHBCFG.TXFELVL) in the AHB configuration register. As long as there is free space in both the non-periodic TxFIFO and the non-periodic request queue, the application can write to transmit data. The available space of both can be checked by reading the host non-periodic transmit FIFO and queue status register (HNPTXSTS).

### 34.3.12 Device FIFO Architecture

Figure 34-6 Schematic Diagram of FIFO Architecture in USBHS Device Mode

#### Device Rx FIFO

USBHS device uses a single receive FIFO to receive data sent to all OUT endpoints. As long as there is free space in the Rx FIFO, the received data packets are sequentially filled into the Rx FIFO. In addition to active data, the received data packet status (including OUT endpoint target number, byte count, data PID, and activation of the received data) is also stored by the module. When no available space exists, the device responds with a NAK to the host transaction and triggers an interrupt on the addressed endpoint. The size of the receive FIFO is configured in the receive FIFO size register (GRXFSIZ).

The single receive FIFO architecture enables USB devices to more efficiently fill the receive RAM buffer:

- All OUT endpoints share the same RAM buffer (shared FIFO)
  - For any host sequence OUT token, the USBHS module can fill the receive FIFO up to its limit
- The application will continuously receive the Rx FIFO non-empty interrupt (RXFNE bit in **USBHS\_GINTSTS**) as long as at least one data packet is available for reading in the Rx FIFO. The application reads data packet information from the receive status read and out-stack register (**GRXSTSP**), and finally retrieves the corresponding data from the receive FIFO by reading the out-stack address associated with the endpoint.

## Device Tx FIFO

The module provides dedicated FIFO for each IN endpoint. The application configures the FIFO size for IN endpoint 0 through Device Endpoint 0 Transmit FIFO Size Register (USBHS\_DIEPTXF0), and configures the FIFO size for IN endpoint x through Device IN Endpoint Transmit FIFO Size Register (USBHS\_DIEPTXFx).

### 34.3.13 FIFO RAM Allocation

#### Host Mode

##### Receive FIFO RAM Allocation

Status information is written to the FIFO with each receive data packet. Therefore, at least (maximum data packet size/4) + 2 space must be allocated for receive data packets. If multiple isochronous channels are enabled, the allocated space for receiving continuous data packets must be at least twice the (maximum data packet size/4) + 2. Generally, the recommended space is twice the (maximum data packet size/4 + 2). This allows the USB to receive subsequent data packets while the previous packet is being transferred to the CPU.

The transmission completion status information and the last received data packet of this endpoint are written together into the FIFO. Therefore, a location must be allocated for this purpose.

When running in DMA mode, the DMA address register of each host channel will be stored in the FIFO. Therefore, one location must be reserved in the FIFO for each channel to store its address register.

##### Transmit FIFO RAM Allocation

The minimum RAM required for the host non-periodic transmit FIFO is the size of the largest data packet transmitted across all supported non-periodic OUT channels.

Typically, the recommended space is twice the maximum packet size, so that while USB is transmitting the current packet, AHB can fill the next packet into the transmit FIFO.

The minimum RAM required for the host to periodically send FIFO is the size of the largest data packet transmitted across all supported periodic OUT channels. If there is at least one isochronous OUT endpoint, the space must be at least twice the maximum packet size in this channel.

When running in DMA mode, the DMA address register of each host channel will be stored in the FIFO. Therefore, one location must be reserved in the FIFO for each channel to store its address register.

#### Device Mode

##### Receive FIFO RAM Allocation

The application should allocate RAM for SETUP packets: 13 locations must be reserved in the receive FIFO to receive SETUP data packets on the control endpoint. The USBHS module will not write any other data to these bits reserved for SETUP data packets. A location will be allocated for the global OUT NAK. Status information is written to the FIFO with each receive data packet. Therefore, at least (maximum packet size/4) + 1 space must be allocated for receive data packets. If multiple isochronous endpoints are enabled, the allocated space for receiving consecutive data packets must be at least twice the (maximum packet size/4) + 1. Generally, the recommended space is twice the (Maximum packet size/4 + 1). This allows the USB to receive subsequent data packets while the previous data packet is being transferred to the CPU.

The transfer completion status information and the last received data packet of this endpoint are pushed into the FIFO together. Normally, it is recommended to allocate one bit for each OUT endpoint.

##### Transmit FIFO RAM Allocation

The minimum RAM space required for each IN endpoint's transmit FIFO is the maximum data packet size of that specific IN endpoint.

#### 34.3.14 System Performance

With a large-capacity RAM buffer, highly configurable FIFO size, 32-bit FIFO fast access via AHB push/pop registers, and especially the advanced FIFO control mechanism, optimal USB and system performance can be achieved. In fact, regardless of the current USB sequence, the USBHS can efficiently fill the available RAM space through this mechanism. With these features:

- The application has enough margin to calculate and correct the CPU load, thereby optimizing CPU bandwidth utilization:
  - ▶ The application can first accumulate a large amount of data to transmit, then send it out via USB.
  - ▶ Provides sufficient timing margin to read data from the receive FIFO.
- The USB module can keep working at full-speed, that is, to provide the maximum full-speed bandwidth (as much hardware as possible to run automatically, and as little software as possible to participate) :
  - ▶ The USB module can accumulate a large amount of sending data in advance at its disposal, enabling automatic management of USB data transmission.
  - ▶ There is ample free space in the receive buffer, which can be automatically filled with data from USB.

The USBHS module can efficiently fill the 8KB RAM buffer, and the 8KB transmit/receive data is sufficient to accommodate the data volume of a full-speed frame. Therefore, the USB system can achieve maximum USB bandwidth within a single frame without application intervention.

#### 34.3.15 Interrupt and Event

There are four types of USBHS interrupts: SOTP mode wake-up interrupt `USBHS_WKUP`, endpoint 1 OUT interrupt `USBHS_EP1_OUT`, endpoint 1 IN interrupt `USBHS_EP1_IN`, and USBHS global interrupt `USBHS_GLB`.

- **USBHS\_WKUP Interrupt**

The `USBHS_WKUP` interrupt is used in STOP mode to wake up the system's STOP mode through `USBHS_DP` or `USBHS_DM`. The interrupt enable bit is `INT_WUPEN`. `USH_WUEN`.

Before using USBHS to wake up the system STOP, you need to ensure that the USBHS controller is in the suspend status, and set the corresponding filter range and enable the filter function in the register `USBHS_SYCTLREG`.

- **USBHS\_EP1\_OUT Interrupt**

The `USBHS_EP1_OUT` interrupt is the OUT interrupt of device mode endpoint 1 that the software needs to handle. The interrupt flag can be queried in `USBHS_DEACHINT`.

- **USBHS\_EP1\_IN Interrupt**

The `USBHS_EP1_IN` interrupt is used for software to handle the IN interrupt of endpoint 1 in device mode. The interrupt flag can be queried in `USBHS_DEACHINT`.

- **USBHS\_GLB Interrupt**

The `USBHS_GLB` interrupt is the main interrupt that the software needs to handle. The flag of the global interrupt can be read in the `USBHS_GINTSTS` register.

Table 34-2 USBHS\_GLB Interrupt Event List

| Interrupt Flag     | Description                                                      | Operating Mode | Internal Event Source |
|--------------------|------------------------------------------------------------------|----------------|-----------------------|
| WKUPINT            | Resume/Remote wake-up interrupt                                  | Host or device | -                     |
| VBUSVINT           | VBUS active interrupt                                            | Device         | -                     |
| DISCINT            | Disconnect interrupt                                             | Host           | -                     |
| CIDSCHG            | Connector ID line status change interrupt                        | Host or device | -                     |
| PTXFE              | Periodic TxFIFO empty interrupt                                  | Host           | -                     |
| LPMINT             | LPM interrupt                                                    | Host or device | -                     |
| HCINT              | Host channel interrupt                                           | Host           | -                     |
| HPRTINT            | Host port interrupt                                              | Host           | -                     |
| DATAFSUSP          | Data acquisition suspend                                         | Device         | -                     |
| IPXFR/INCOMPISOOUT | Incomplete periodic transfer/Incomplete OUT isochronous transfer | Device         | -                     |
| IISOIXFR           | Incomplete IN isochronous transfer                               | Device         | -                     |
| OEPINT             | OUT endpoint interrupt                                           | Device         | -                     |
| IEPINT             | IN endpoint interrupt                                            | Device         | -                     |
| EOPF               | Periodic frame end interrupt                                     | Device         | -                     |
| ISOODRP            | Discard synchronization OUT data packet interrupt                | Device         | -                     |
| ENUMDNE            | Enumeration complete                                             | Device         | -                     |
| USBRST             | USB reset interrupt                                              | Device         | -                     |
| USBSUSP            | USB suspend interrupt                                            | Device         | -                     |
| ESUSP              | Early suspend interrupt                                          | Device         | -                     |
| GONAKEFF           | Global OUT NAK active interrupt                                  | Device         | -                     |
| GINAKEFF           | Global non-periodic IN NAK active interrupt                      | Device         | -                     |
| NPTXFE             | Non-periodic TxFIFO empty interrupt                              | Host           | -                     |
| RXFNE              | RxFIFO not empty interrupt                                       | Host or device | -                     |
| SOF                | Frame start interrupt                                            | Host or device | Yes                   |
| MMIS               | Mode mismatch interrupt                                          | Host or device | -                     |

## 34.4 Programming Module

### 34.4.1 Module Initialization

#### Context

The application must perform the module initialization sequence. For details on how to determine the mode, see [Mode Decision](#).

This section describes the initialization process after power-on of the USBHS controller. Whether working in host mode or device mode, the application must follow the initialization sequence. Initialize all module global registers based on the module configuration:

#### Procedure

- Step1.** Program the following fields in the USBHS\_GAHBCFG register:
  - Global interrupt mask bit GINTMSK=1
  - RxFIFO not empty (RXFNE bit in USBHS\_GINTSTS)
  - Periodic TxFIFO empty threshold
- Step2.** Program the following fields in the USBHS\_GUSBCFG register:
  - FS timeout calibration field
  - USB turnaround time field
- Step3.** The software must unmask the following bits in the USBHS\_GINTMSK register:
  - Mode mismatch interrupt mask
- Step4.** By reading the CMOD bit in USBHS\_GINTSTS, the software can determine whether the USBHS controller is operating in host mode or device mode.

### 34.4.2 Host Initialization

#### Context

To initialize the module as the host, the application must perform the following steps:

#### Procedure

- Step1.** Program USBHS\_GINTMSK.HPRTIM bit to 1 to unmask the interrupt.
- Step2.** Program the USBHS\_HCFG register to select full-speed host.
- Step3.** Program the PWPR bit in USBHS\_HPRT to 1 to supply VBUS to the USB bus.
- Step4.** Wait for the PCDET interrupt in USBHS\_HPRT. This indicates that a device is connected to the host port.
- Step5.** Program the PRST bit in USBHS\_HPRT to 1 to issue a reset signal on the USB bus.
- Step6.** Wait at least 10ms for allow the reset process to complete.
- Step7.** Program the PRST bit in USBHS\_HPRT to 0.
- Step8.** Wait for the PENCHNG interrupt in USBHS\_HPRT.
- Step9.** Read the PSPD bit in USBHS\_HPRT to obtain the enumeration speed.
- Step10.** Use the selected PHY clock and configure the HFIR register accordingly.
- Step11.** Program the FSLSPCS field in the USBFS\_HCFG register according to the device speed detected in Step 9. If the FSLSPCS is modified, a port reset must be performed.
- Step12.** Program the USBHS\_GRXFSIZ register to select the receive FIFO size.
- Step13.** Program the USBFS\_HNPTXFSIZ register to select the size and start address of the non-periodic transmit FIFO for non-periodic communication transactions.
- Step14.** Program the USBFS\_HPTXFSIZ register to select the size and start address of the periodic communication transmit FIFO for periodic communication transactions.

## Post Request

To communicate with the device, the system software must initialize and enable at least one channel.

### 34.4.3 Device Initialization

#### Context

During power on or after switching from host mode to device mode, the application must perform the following steps to initialize the module as a device.

#### Procedure

- Step1.** Program the following fields in the USBHS\_DCFG register:
  - Device speed
  - Non zero length status OUT handshake signal
- Step2.** Program the USBHS\_GINTMSK register to unmask the following interrupts:
  - USB reset
  - Enumeration complete
  - Early suspend
  - USB suspend
  - SOF
- Step3.** Wait for the VBUSVINT interrupt in USBHS\_GINTSTS, indicating the power supply state is entered.
- Step4.** Wait for the USBRST interrupt in USBHS\_GINTSTS. This indicates that a reset signal has been detected on the USB, and the reset process lasts approximately 10ms after receiving this interrupt.
- Step5.** Wait for the ENUMDNE interrupt in USBHS\_GINTSTS. This interrupt indicates the end of the reset process on USB. Upon receiving this interrupt, the application must read the USBHS\_DSTS register to determine the enumeration speed and perform the steps listed in the endpoint initialization on enumeration completion.

#### Results

At this point, the device is ready to receive SOF data packets and perform control transfers on control endpoint 0.

### 34.4.4 DMA Mode

The USB uses the AHB host interface to fetch transmit data packet data (AHB to USB) and receive data updates (USB to AHB). The AHB host interface uses programmed DMA address (HCDMAx register in host mode and DIEPDMAx/DOEPDMAx registers in device mode) to access data buffers.

### 34.4.5 Host Programming Model

#### 34.4.5.1 Channel Initialization

##### Context

The application must initialize one or more channels before communicating with the connected devices.

To initialize and enable the channel, the application must perform the following steps:

##### Procedure

- Step1.** Program the USBHS\_GINTMSK register to unmask the interrupt for the following bits:

- The non-periodic transmit FIFO for OUT transactions is empty (applicable when working at the pipeline transaction level and the programmed packet count field value is greater than 1).
- The non-periodic transmit FIFO for OUT transactions is half-empty (applicable when working at the pipeline transaction level and the programmed packet count field value is greater than 1).

**Step2.** Program the USBHS\_HAINTMSK register to enable the selected channel interrupt.

**Step3.** Program the USBHS\_HCINTMSK register to enable the interrupts related to communication transactions reflected in the host channel interrupt register.

**Step4.** Program the selected channel's USBHS\_HCTSIZx register to specify the total transmission size in bytes and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (used for the first OUT transaction or expected to be obtained from the first IN transaction).

**Step5.** Program the selected channel's USBHS\_HCCHARx register to specify the endpoint features of the device, such as type, speed, direction, etc. (Only when the application is ready to send or receive data packets can the channel be enabled by setting the channel enable bit to 1.)

#### 34.4.5.2 Channel Halted

The application can disable any channel by programming the USBHS\_HCCHARx registers by setting the CHDIS and CHENA bits to 1. This will cause the USBHS host to clear any previously issued requests on this channel (if any) and generate a channel stop interrupt. The application must wait for the CHH interrupt in USBHS\_HCINTx before reassigning the channel to other communication transactions. The USBHS host will not interrupt communication transactions already initiated on the USB.

Before disabling a channel, the application must ensure that there is at least one free space in the non-periodic request queue (when disabling non-periodic channels) or the periodic request queue (when disabling periodic channels). The application can clear the request queue by programming the USBHS\_HCCHARx register to set the CHDIS bit to 1 and clear the CHENA bit to 0 when the request queue is full (before disabling the channel). The application will disable the channel when any of the following conditions occur:

- STALL, TXERR, BBERR or DTERR interrupt received in USBHS\_HCINTx of IN or OUT channel. The application must be capable of receiving other interrupts (DTERR, Nak, Data, TXERR) from the same channel before receiving the channel stop signal.
- Received a DISCINT (disconnect device) interrupt in USBHS\_GINTSTS. (The application will disable all enabled channels).
- The application aborted the transfer before it could complete normally.

When in DMA mode, the application cannot stop an integral periodic transfer by writing to the register.

#### 34.4.5.3 Ping Protocol

When the USBHS host operates in high-speed mode and the application needs to communicate with a high-speed bulk or control (data and status stage) OUT endpoint, the ping protocol must be used.

When the application receives a NAK/NYET/TXERR interrupt, the ping protocol must be applied. Upon receiving any of the above responses, the USBHS host discontinues any communication transactions on that endpoint. It discards all issued or fetched OUT requests (from the request queue) and clears the corresponding data from the transmit FIFO.

This is only applicable in device mode. In device mode, the application can send a ping token in two ways: By setting the DOPING bit in the HCTSIZx register before enabling the channel; or by writing

to the HCTSIZx register and setting the DOPING bit after the channel has already been enabled. This enables the USBHS host to write the ping request into the request queue. The application must wait for the device's response to the ping token (NAK, ACK, or TXERR interrupt) before proceeding with the communication transaction or sending another ping token. The application may only proceed with data communication transactions after receiving an ACK response from the device's OUT endpoint to the ping token. When operating in DMA mode, for bulk/control OUT transactions, the application does not need to set the DOPING bit in HCTSIZx upon receiving a NAK/NYET response. The USBHS host automatically sets bit 1 of the DOPING field in the HCTSIZx register, and then issues a ping token during bulk/control OUT transfers. The USBHS host continues to send ping tokens until an ACK is received, after which it automatically switches to the data communication transaction.

### 34.4.6 Device Programming Model

#### 34.4.6.1 Endpoint Initialization on USB Reset

##### Procedure

- Step1.** Set the NAK bit to 1 for all OUT endpoints
  - In USBHS\_DOEPCTLx, SNAK=1 (for all OUT endpoints)
- Step2.** Unmask the following interrupt bits
  - In USBHS\_DAINMSK, INEP0=1 (control 0 IN endpoint)
  - In USBHS\_DAINMSK, OUTEP0=1 (control 0 OUT endpoint)
  - In DOEPMSK, STUP=1
  - In DOEPMSK, XFRC=1
  - In DIEPMSK, XFRC=1
  - In DIEPMSK, TOC=1
- Step3.** Configure data FIFO RAM for each FIFO
  - Program the USBHS\_GRXFSIZ register to enable receiving OUT data and setup data for control transfers. This register must be at least equal to 1 maximum packet size for control endpoint 0+2 words (for control OUT packet status) + 10 words (for SETUP packet).
  - Program the USBHS\_TX0FSIZ register (depending on the selected FIFO number) to enable transmit control IN data. The register must be at least equal to 1 maximum packet size of control endpoint 0.
- Step4.** Program the following fields in the endpoint-related register to enable control OUT endpoint 0 to receive SETUP packets
  - In USBHS\_DOEPTSIZE0, STUPCNT=3 (receives up to 3 consecutive SETUP packets)

##### Results

At this point, all initialization work required for receiving SETUP packets is completed.

#### 34.4.6.2 Endpoint Initialization Upon USB Enumeration Completion

##### Procedure

- Step1.** Upon enumeration completion interrupt (ENUMDNE in USBHS\_GINTSTS), read the USBHS\_DSTS register to determine the device's enumeration speed.
- Step2.** Program the MPSIZ field in USBHS\_DIEPCTL0 to set the maximum packet size. This step configures control endpoint 0. The maximum packet size of the control endpoint depends on the enumeration speed.

## Results

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

### 34.4.6.3 Endpoint Initialization Upon Receiving the SetAddress Command

#### Context

This section describes the operations that the application must perform when receiving a SetAddress command in the SETUP packet.

#### Procedure

- Step1.** Program the USBHS\_DCFG register using the device address received in the SetAddress command.
- Step2.** Program the module to issue an IN data packet during the status phase.

### 34.4.6.4 Endpoint Initialization When a SetConfiguration/SetInterface Command is Received

#### Context

This section describes the operations that the application must perform upon receiving a SetConfiguration or SetInterface command in the SETUP packet.

#### Procedure

- Step1.** Upon receiving the SetConfiguration command, the application must program the endpoint registers to configure them using the features of active endpoints in the new configuration.
- Step2.** Upon receiving the SetInterface command, the application must program the endpoint register of the endpoint specified by the command.
- Step3.** Endpoints that were active in previous configurations or other settings become inactive in new configurations or other settings. These inactive endpoints must be disabled.
- Step4.** Use the USBHS\_DAINMSK register to enable interrupts for active endpoints and mask interrupts for inactive endpoints.
- Step5.** Set up data FIFO RAM for each FIFO.
- Step6.** After configuring all required endpoints, the application must program the module to transmit IN packets for the status stage.

## Results

At this point, the device module is ready to receive and transmit any type of data packet.

### 34.4.6.5 Endpoint Activation

#### Context

This section describes the steps required to activate a device endpoint or configure an existing device endpoint as a new type.

#### Procedure

- Step1.** In the USBHS\_DIEPCTLx register (for IN or bidirectional endpoints) or USBHS\_DOEPCTLx register (for OUT or bidirectional endpoints), program the features of the desired endpoint in the following fields.
  - Maximum packet size
  - USB active endpoint bit set to 1
  - Endpoint initial data synchronization bit (for interrupt and bulk endpoints)
  - Endpoint type
  - TxFIFO number

- Step2.** After the endpoint is enabled, the module starts decoding tokens sent to the endpoint and replies with a active handshake signal if the received token is enabled.

#### 34.4.6.6 Endpoint Disabled

##### Context

This section describes the steps required to disable an existing endpoint.

##### Procedure

- Step1.** To disable an endpoint, clear the USB active endpoint bit in the USBHS\_DIEPCTLx register (for IN or bidirectional endpoints) or the USBHS\_DOEPCTLx register (for OUT or bidirectional endpoints).
- Step2.** When an endpoint is disabled, the module ignores tokens sent to it, causing a USB timeout.

## 34.5 Operational Module

### 34.5.1 SETUP and OUT Data Transmission

This section describes the internal data flow and application operation steps during data OUT transfers and SETUP transactions.

#### Packet Reading

This section describes how to read data packets (OUT and SETUP data packets) from the receive FIFO.

1. When the RXFNE interrupt (USBHS\_GINTSTS register) is captured, the application must read the receive status pop up register (USBHS\_GRXSTSP).
2. The application can mask the RXFNE interrupt (in USBHS\_GINTSTS) by writing RXFNE=0 (in USBHS\_GINTMSK) until it reads the data packet from the receive FIFO.
3. If the byte counting of the received packet is not 0, pop up these data from the receive data FIFO and store them in memory. If the byte counting of the received packet is 0, no data will be popped from the receive data FIFO.
4. The packet status read from the receive FIFO has the following states:
  - Global OUT NAK:  
PKTSTS=Global OUT NAK, BCNT=0x000, the values of EPNUM and DPID are irrelevant.  
These data indicate that the global OUT NAK bit has taken effect.
  - SETUP packet:  
PKTSTS=SETUP, BCNT=0x008, EPNUM=Control EP number, DPID=D0. These data indicate that SETUP packets received on the specified endpoint can now be read from the receive FIFO.
  - Establishment phase completed:  
PKTSTS=Setup phase complete, BCNT=0x0, EPNUM=Control EP number, DPID value is irrelevant.  
This data indicates that the setup phase of the specified endpoint is complete and the data phase has been initiated. After this status entry pops from the receive FIFO, the module will generate a setup interrupt on the corresponding control OUT endpoint.
  - OUT packet:  
PKTSTS=DataOUT, BCNT=Size of received OUT data packet (BCNT: 0-1024), EPNUM=Endpoint number of the received data packet, DPID=Actual data PID.
  - Data transmission complete:  
PKTSTS=OUT data transmission complete, BCNT=0x0, EPNUM=OUT EP number that completed data transmission, DPID value is irrelevant.  
This data indicates the completion of OUT data transmission at the specified OUT endpoint. After this status entry pops from the receive FIFO, the module will trigger a "Transmission Complete" interrupt on the designated OUT endpoint.
5. After popping data from the receive FIFO, the RXFNE interrupt must be unmasked (USBHS\_GINTSTS).
6. Each time the application detects an RXFNE interrupt in USBHS\_GINTSTS, steps 1 through 5 will be repeated. Reading an empty receive FIFO may result in undefined module behavior.

#### SETUP Transaction

Describe the block's method for handling SETUP packets and the sequence for application processing of SETUP transactions.

#### Application Requirements:

1. To receive a SETUP packet, the control OUT endpoint STUPCNT field (USBHS\_DOEPTSIZE) must be programmed to a non-zero value. If the application programs the STUPCNT field to a non-zero value, the module will receive the SETUP packet and write it to the receive FIFO, regardless of the NAK status and the EPENA bit setting in USBHS\_DOEPTCTL. For each SETUP packet received by the control endpoint, the STUPCNT field decrements. If the STUPCNT field is not programmed to the appropriate value before receiving the SETUP packet, the module can still receive the SETUP packet and decrement the STUPCNT field. However, the application may not be able to determine the correct number of SETUP packets received during the setup phase of the control transmission.
  - In USBHS\_DOEPTSIZE, STUPCNT=3
2. The application must always allocate some additional space in the receive data FIFO to accommodate up to three consecutive SETUP packets on the control endpoint.
  - Reserved space of 10 words. The first SETUP packet requires 3 words, the "Setup Phase Complete" status double-word requires 1 word, and an additional 6 words are needed to store two extra SETUP packets.
  - Each SETUP packet requires 3 words to store 8 bytes of SETUP data and 4 bytes of SETUP status. The module will reserve these spaces in the receive FIFO.
  - This FIFO is exclusively used for storing SETUP packets and will never utilize this space for data packets.
3. The application must read 2 words of SETUP data packet from the receive FIFO.
4. The application must read and discard the "Establishment Phase Complete" status word from the receive FIFO.

#### Internal Data Flow:

1. Upon receiving a SETUP packet, the module writes the received data into the receive FIFO without checking the available space in the receive FIFO, regardless of the endpoint's NAK and STALL bit settings.
  - The module internally sets the IN NAK and OUTNAK bits of the control IN/OUT endpoints that receive the SETUP packet to 1.
2. For each SETUP packet received over USB, the module writes 3 words of data into the receive FIFO and decrements the STUPCNT field by 1.
  - The first word contains internal control information used by the module.
  - The second word contains the first 4 bytes of the SETUP command.
  - The third word contains the last 4 bytes of the SETUP command.
3. When the setup phase ends and the data IN/OUT phase starts, the block writes a status entry ("Setup Phase Complete" word) into the receive FIFO, indicating the setup phase is complete.
4. On the AHB side, the SETUP packet is read by the application.
5. When the application pops the "Setup Phase Complete" word from the receive FIFO, the module will interrupt the application using the STUP interrupt (USBHS\_DOEPTINT), indicating that it can process the received SETUP packet.
  - The module will clear the endpoint enable bit of control OUT endpoint.

#### Application Programming Sequence:

1. Program the USBHS\_DOEPTSIZE register.
  - STUPCNT=3
2. Wait for the RXFNE interrupt (USBHS\_GINTSTS) and read the data packet from the receive FIFO.
3. The STUP interrupt trigger (USBHS\_DOEPTINT) indicates the successful completion of SETUP data transmission.

- When this interrupt occurs, the application must read the USBHS\_DOEPTSIZx register to determine the number of received SETUP packets and process the last received SETUP packet.

#### Process More Than Three Consecutive SETUP Packets:

According to the USB2.0 specification, the host typically does not send more than three consecutive SETUP packets to the same endpoint during SETUP packet errors. However, the USB 2.0 specification does not limit the number of consecutive SETUP packets that the host can send to the same endpoint. When this occurs, the USBHS controller will generate an interrupt (B2BSTUP in USBHS\_DOEPINTx).

### Set Global OUT NAK to 1

#### Internal Data Flow:

1. If the application sets the global OUT NAK (SGONAK bit in USBHS\_DCTL) to 1, the module will stop writing any data other than SETUP packets to the receive FIFO. Regardless of the available space size in the receive FIFO, the device will respond with a NAK to asynchronous OUT tokens sent by the host, while directly ignoring synchronous OUT data packets.
2. The module writes the global OUT NAK to the receive FIFO. The application must reserve sufficient space for this.
3. When the application pops the global OUT NAK word from the receive FIFO, the block sets the GONAKEFF interrupt (USBHS\_GINTSTS) to 1.
4. When the application detects this interrupt, it will assume the module is in global OUT NAK mode. The application can clear this interrupt by clearing the SGONAK bit in USBHS\_DCTL.

#### Application Programming Sequence:

1. To stop receiving any type of data into the receive FIFO, the application must program the following fields to set the global OUT NAK bit to 1.
  - In USBHS\_DCTL, SGONAK=1
2. Wait for the GONAKEFF interrupt in USBHS\_GINTST. Once triggered, this interrupt indicates that the module has stopped receiving any type of data except SETUP packets.
  - If the application has set the SGONAK bit in USBHS\_DCTL to 1, the application can receive active OUT packets before the module generates a GONAKEFF interrupt (USBHS\_GINTSTS).
3. Applications can temporarily mask this interrupt by writing to the GINAKEFFM bit in the USBHS\_GINTMSK register.
  - In the USBHS\_GINTMSK register, GINAKEFFM=0
4. When the application is ready to exit the global OUT NAK mode, the SGONAK bit in USBHS\_DCTL must be cleared. This operation also clears the GONAKEFF interrupt (USBHS\_GINTSTS).
  - In CGONAK, USBHS\_DCTL=1
5. If the application has previously masked this interrupt, the interrupt must be unmasked as follows:
  - In GINTMSK, GINAKEFFM=1

### Disable the Enabled OUT Endpoint

The application must disable the enabled OUT endpoint using the following sequence.

#### Application Programming Sequence:

1. Before disabling any OUT endpoint, the application must enable the global OUT NAK mode in the module.
  - In USBHS\_DCTL, SGONAK=1
2. Wait for the GONAKEFF interrupt (USBHS\_GINTSTS)
3. Disable the OUT endpoint by programming the following fields:

- In USBHS\_DOEPTCTLx, EPDIS=1
  - In USBHS\_DOEPTCTLx, SNAK=1
4. Wait for the EPDISD interrupt (USBHS\_DOEPTINTx), which indicates that the OUT endpoint has been completely disabled. When an EPDISD interrupt is triggered, the module will also clear the following bits:
    - In USBHS\_DOEPTCTLx, EPDIS=0
    - In USBHS\_DOEPTCTLx, EPENA=0
  5. The application must clear the global OUT NAK bit to start receiving data from other OUT endpoints that are not disabled.
    - In USBHS\_DCTL, SGONAK=0

### Universal Asynchronous OUT Data Transmission

This section describes a general asynchronous OUT data transfer (control, bulk or interrupt).

#### Application Requirements:

1. Before establishing an OUT transfer, the application must allocate a buffer in memory to hold all the data to be received as part of the OUT transfer.
2. For OUT transfer, the transfer size field in the endpoint's transfer size register must be a multiple of the endpoint's maximum packet size (and word-aligned).
  - $\text{Transfer Size}[\text{EPNUM}] = n \times (\text{MPSIZ}[\text{EPNUM}] + 4 - (\text{MPSIZ}[\text{EPNUM}] \bmod 4))$
  - $\text{Packet Count}[\text{EPNUM}] = n$
  - $n > 0$
3. When an OUT endpoint interrupt occurs, the application must read the endpoint's transfer size register to calculate the amount of active data in memory. The received active data amount may be less than the programmed transfer size.
  - $\text{Active data amount in memory} = \text{Initial transfer amount set by application program} - \text{remaining transfer amount after module update}$
  - $\text{Number of received USB data packets} = \text{Initial number of packets set by application} - \text{remaining number of packets after module update}$

#### Internal Data Flow:

1. The application must set the transfer size and packet count fields in the endpoint-related register, clear the NAK bit, and enable the endpoint to receive data.
2. After the NAK bit is cleared, the module starts to receive data and writes the data into the receive FIFO (as long as there is space in the receive FIFO). For each data packet received over USB, the packet and its status are written to the receive FIFO. Each packet (either a packet with data volume reaching the maximum packet size or a short packet) written to the receive FIFO will decrement the packet count field of this endpoint by 1.
  - If the received packet has an inactive CRC, it is automatically cleared from the receive FIFO.
  - After replying with an ACK for the data packet on USB, the module discards the non-isochronous OUT packet retransmitted by the host due to undetected ACK. The application will not detect multiple consecutive OUT packets on the same endpoint with identical data PIDs. In this case, the packet count does not decrement.
  - If there is no space in the receive FIFO, isochronous or asynchronous packets will be ignored and not written into the receive FIFO. In addition, an asynchronous OUT token will receive a NAK handshake response.

- In all three scenarios mentioned above, the packet count will not decrement as no data is written to the receive FIFO.
- 3. When the packet count becomes 0 or a short packet is received on the endpoint, the NAK bit of that endpoint will be set to 1. When the NAK bit is set to 1, both synchronous and asynchronous data packets will be ignored and not written into the receive FIFO. Additionally, asynchronous OUT tokens will receive a NAK handshake response.
- 4. After data is written to the receive FIFO, the application will read data from the receive FIFO and write it to external storage, one packet at a time, endpoint by endpoint.
- 5. After writing each data packet to the external storage via AHB, the endpoint's transmission size is automatically decremented by the size of the data packet.
- 6. Under the following conditions, the OUT data transmission completion status of the OUT endpoint will be written to the receive FIFO:
  - Transfer size is 0 and packet count is 0
  - The last OUT data packet written to the receive FIFO is a short packet (Packet size: 0 to maximum packet size-1)
- 7. When the application pops this status entry (OUT data transfer completed) and generates a transfer completed interrupt for this endpoint, it also clears the endpoint enable bit.

#### Application Programming Sequence:

1. Program the USBHS\_DOEPTSIZE register using the transfer size and corresponding packet count.
2. Program the USBHS\_DOEPCTL register using endpoint features, and set the EPENA and CNAK bits to 1.
  - In USBHS\_DOEPCTL, EPENA=1
  - In USBHS\_DOEPCTL, CNAK=1
3. Wait for the RXFNE interrupt (in USBHS\_GINTSTS) and read the data packet from the receive FIFO.
  - This step can be repeated multiple times, depending on the transfer size.
4. Trigger the XFRC interrupt (USBHS\_DOEPINT) to indicate the successful completion of an asynchronous OUT data transmission.
5. Read the USBHS\_DOEPTSIZE register to determine the active data amount.

#### Universal Synchronous OUT Data Transmission

This section describes regular synchronous OUT data transmission.

#### Application Requirements:

1. All application requirements for asynchronous OUT data transmissions apply equally to synchronous OUT data transmission
2. For synchronous OUT data transmissions, the transmission size and packet count fields must always be set to the number of packets corresponding to the maximum packet size receivable in a single frame. Synchronous OUT data transmission transactions must be completed within a single frame.
3. Before the periodic frame ends (EOPF interrupt in USBHS\_GINTSTS), the application must read all synchronous OUT packets (data entries and status entries) from the receive FIFO.
4. To receive data in the next frame, a synchronous OUT endpoint must be enabled after EOPF (USBHS\_GINTSTS) and before SOF (USBHS\_GINTSTS).

#### Internal Data Flow:

1. The internal data flow of synchronous OUT endpoints is essentially the same as that of asynchronous OUT endpoints, with minor differences.

2. When enabling a synchronous OUT endpoint by setting the endpoint enable bit to 1 and clearing the NAK bit, the corresponding even/odd frame bit must also be set to 1. The module will receive data from a specific frame on the synchronized OUT endpoint only when the following conditions are met:
  - EONUM (in USBHS\_DOEPTCTLx)=FNSOF[0] (in USBHS\_DSTS)
3. When the application reads a complete synchronous OUT packet (data and status) from the receive FIFO, the module updates the RXDPID field in USBHS\_DOEPTSIz based on the data PID of the last synchronous OUT packet read from the receive FIFO.

#### Application Programming Sequence:

1. Program the USBHS\_DOEPTSIz register using the transmission size and corresponding packet count.
2. Program the USBHS\_DOEPTCTLx register using endpoint features, and set the endpoint enable bit, clear NAK bit, and odd/even frame bit to 1.
  - EPENA1
  - CNAK=1
  - EONUM=(0: Even/1: Odd)
3. Wait for the RXFNE interrupt (in USBHS\_GINTSTS) and read the data packet from the receive FIFO.
  - This step can be repeated multiple times, depending on the transfer size.
4. XFRC interrupt (in USBHS\_DOEPTINTx) indicates the completion of a synchronous OUT data transmission. This interrupt does not necessarily indicate that the data in memory is enabled.
5. For synchronous OUT transfers, the application may not always detect this interrupt. Instead, the application may detect the IISOXFRM interrupt in USBHS\_GINTSTS.
6. Read the USBHS\_DOEPTSIz register to determine the received transmission size and verify the activity of the received data within the frame. The application shall consider the received data in memory as active only when one of the following conditions is met:
  - RXDPID=D0 (in USBHS\_DOEPTSIz) and the number of active USB data packets received=1
  - RXDPID=D1 (in USBHS\_DOEPTSIz) and the number of active USB data packets received=2
  - RXDPID=D2 (in USBHS\_DOEPTSIz) and the number of active USB data packets received=3

The number of USB packets receiving active data=Initial packet count programmed by the application-remaining packet count after module update.

The application can discard inactive packets.

#### Incomplete Synchronous OUT Data Transmission

This section describes the application programming sequence when packet loss occurs in synchronous OUT data packets.

##### Internal Data Flow:

1. For synchronous OUT endpoints, the XFRC interrupt (in USBHS\_DOEPTINTx) may not always be triggered. If the module discards the synchronized OUT data packet, the application may fail to detect the XFRC interrupt (USBHS\_DOEPTINTx) under the following conditions:
  - When the receive FIFO cannot accommodate a complete ISO OUT packet, the module will discard the received ISO OUT data.
  - The received synchronization OUT packet has a CRC error.
  - The module received a corrupted synchronization OUT token.
  - The application reads data from the receive FIFO at a very slow speed.
2. If the block detects a periodic frame end before the transfer completion of all synchronous OUT endpoints, it will trigger an incomplete synchronous OUT data interrupt (IISOXFRM in USBHS\_GINTSTS),

indicating that at least one synchronous OUT endpoint did not trigger an XFRC interrupt (in USBHS\_DOEPINTx). At this time, endpoints with unfinished transfers remain enabled, but there are no ongoing active transfers on this USB endpoint.

#### Application Programming Sequence:

1. Hardware triggers the IISOXFRM interrupt (USBHS\_GINTSTS) indicating that at least one synchronous OUT endpoint has an incomplete transfer in the current frame.
2. If this occurs due to incomplete reading of synchronous OUT data from the endpoint, the application must ensure all synchronous OUT data (including data entries and status entries) are first read from the receive FIFO before proceeding with further processing.
  - After reading all data from the receive FIFO, the application can detect the XFRC interrupt (USBHS\_DOEPINTx). In this case, the application must re-enable the endpoint to receive synchronous OUT data in the next frame.
3. When the application receives the IISOXFRM interrupt (in USBHS\_GINTSTS), it must read the control registers (USBHS\_DOEPCTLx) of all synchronous OUT endpoints to determine which endpoints have incomplete transmission in the current frame. When both of the following conditions are met simultaneously, it indicates that the endpoint transfer is incomplete:
  - EONUM bit (in USBHS\_DOEPCTLx) = FNSOF[0] (in USBHS\_DSTS)
  - EPENA=1 (in USBHS\_DOEPCTLx)
4. Before detecting the SOF interrupt (in USBHS\_GINTSTS), the previous operation must be fully completed to ensure the current frame number has not changed.
5. For synchronous OUT endpoints with incomplete transmission, the application must discard the data in memory and disable the endpoint by setting the EPDIS bit in USBHS\_DOEPCTLx to 1.
6. Wait for the EPDIS interrupt (in USBHS\_DOEPINTx), and enable the endpoint to receive new data in the next frame.
  - Since the module may require some time to disable the endpoint, the application may fail to receive data in the next frame after detecting inactive synchronization data.

#### Disable Asynchronous OUT Endpoint

This section describes how the application can stop an asynchronous endpoint.

1. Place the module in global OUT NAK mode.
2. Disable the required endpoint
  - When disabling an endpoint, please set STALL=1 (in USBHS\_DOEPCTL) instead of setting the SNAK bit to 1 in USBHS\_DOEPCTL. The priority of the STALL bit is always higher than that of the NAK bit.
3. When the application no longer needs the endpoint to respond with a STALL handshake, the STALL bit (in USBHS\_DOEPCTLx) must be cleared to zero.
4. If an application receives a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command from the host to set or clear the STALL state of an endpoint, it must set the STALL bit to 1 or clear it on the control endpoint before initiating the status phase transfer.

### 34.5.2 IN Data Transmission

#### Packet Write

This section describes how the application writes data packets to the endpoint FIFO when the dedicated transmit FIFO is enabled.

1. The application can choose between polling mode or interrupt mode.

- In polling mode, the application monitors the status of the endpoint transmit data FIFO by reading the USBHS\_DTXFSTSx register to determine whether there is sufficient space in the data FIFO.
  - In interrupt mode, the application waits for the TXFE interrupt (in USBHS\_DIEPINTx), then reads the USBHS\_DTXFSTSx register to determine if there is sufficient space in the data FIFO.
  - To write a single non-zero length packet, there must be sufficient space in the data FIFO to accommodate the entire packet.
  - To write a zero length packet, the application cannot check the FIFO space.
2. If one of the above methods is used, when the application determines there is sufficient space to write transmit data packets, the application must first perform the corresponding write operation to the endpoint control register before writing data to the data FIFO. Typically, the application must perform a read-modify-write operation on the USBHS\_DIEPCTLx register to avoid modifying other contents in the register while setting the endpoint enable bit to 1.  
If sufficient space is available, the application can write multiple data packets for the same endpoint into the transmit FIFO. For periodic IN endpoints, the application can only write multiple data packets within a single frame at a time. The application will only write all packets to be sent in the next frame after the previous frame's communication transaction has completed.

### Set IN Endpoint NAK to 1

#### Internal Data Flow:

1. When the application sets the IN NAK of a specific endpoint to 1, the module will stop data transmission on that endpoint, regardless of whether data is available in the endpoint's transmit FIFO.
2. The asynchronous endpoint receives the IN token and replies with a NAK handshake response.
  - The synchronous endpoint receives an IN token and returns a zero length data packet.
3. The module triggers the INEPNE (IN endpoint NAK active) interrupt in USBHS\_DIEPINTx in response to the SNAK bit in USBHS\_DIEPCTLx.
4. When the application detects this interrupt, it will consider the endpoint to be in IN NAK mode. The application can clear this interrupt by setting the CNAK bit in USBHS\_DIEPCTLx to 1.

#### Application Programming Sequence:

1. To stop sending any data on a specific IN endpoint, the application must set the IN NAK bit to 1. To set this bit to 1, the following fields must be programmed.
  - SNAK=1 in USBHS\_DIEPCTLx
2. Wait for the INEPNE interrupt in USBHS\_DIEPINTx to trigger. This interrupt indicates the module has stopped transmitting data on the endpoint.
3. The module can send active IN data on the endpoint when the application sets the NAK bit to 1 but the "NAK Active" interrupt has not yet been triggered.
4. The application can temporarily mask this interrupt by writing to the INEPNEM bit in DIEPMSK.
  - In DIEPMSK, INEPNEM=0
5. To exit endpoint NAK mode, the application must clear the NAK status bit (NAKSTS) in USBHS\_DIEPCTLx. This action also clears the INEPNE interrupt (in USBHS\_DIEPINTx).
  - In USBHS\_DIEPCTLx, CNAK=1
6. If the application has masked this interrupt, it must be unmasked as follows:
  - In DIEPMSK, INEPNEM=1

### Disable IN Endpoint

Use the following sequence to disable a previously enabled specific IN endpoint.

#### Application Programming Sequence:

1. The application must first stop writing data on the AHB before disabling the IN endpoint.
2. The application must set the endpoint to NAK mode.
  - SNAK=1 in USBHS\_DIEPCTLx
3. Wait for the INEPNE interrupt in USBHS\_DIEPINTx.
4. The following bits in the USBHS\_DIEPCTLx register of the endpoint that must be disabled must be set to 1.
  - EPDIS=1 in USBHS\_DIEPCTLx.
  - SNAK=1 in USBHS\_DIEPCTLx
5. The EPDISD interrupt in USBHS\_DIEPINTx indicates that the block has completely disabled the specified endpoint. At the same time the interrupt is triggered, the module also clears the following bits:
  - In USBHS\_DIEPCTLx, EPENA=0
  - In USBHS\_DIEPCTLx, EPDIS=0
6. The application must read the USBHS\_DIEPTSIZx register for periodic IN EP to calculate the amount of data transmitted on the endpoint via USB.
7. The application must clear the data in the endpoint transmit FIFO by setting the following fields in the USBHS\_GRSTCTL register to 1:
  - TXFNUM (in USBHS\_GRSTCTL)=Transmit FIFO number of the endpoint
  - TXFFLSH (in USBHS\_GRSTCTL)=1

The application must poll the USBFS\_GRSTCTL register until the module clears the TXFFLSH bit, indicating the FIFO flush operation has ended. To send new data on this endpoint, the application can re-enable the endpoint later.

### Universal Non-periodic IN Data Transmission

#### Application Requirements:

1. Before establishing an IN transmission, the application must ensure that each data packet comprising an IN transmission, can fit into a single buffer.
2. For IN transmission,s, the transmission size field in the endpoint transmission size register indicates the active data amount of the current transmission, which consists of multiple maximum packet sizes and a single short packet. The short data packet is sent at the end of transmission.
  - To send multiple packets of the maximum packet size and append a short packet at the end of transmission.  
 Transmission size [EPNUM]= $x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$   
 If ( $\text{sp} > 0$ ), packet count[EPNUM]= $x + 1$ .  
 Otherwise, packet count [EPNUM]= $x$
  - To send a single zero length data packet:  
 Transmission size[EPNUM]=0  
 Packet count[EPNUM]=1
  - To send multiple packets of the maximum packet size and append a zero length packet at the end of transmission, the application must split the transfer into two parts.  
 The first part transmits a packet with the maximum packet size, while the second part transmits only a zero length packet.  
 First transfer: transmission size[EPNUM]= $x \times \text{MPSIZ}[\text{epnum}]$ ; Packet count= $n$ ;  
 Second transfer: transmission size[EPNUM]=0; Packet count=1;

3. After enabling an endpoint for data transmission, the module updates the transmission size register. At the IN transmission end, the application must read the transmission size register to determine how much data in the transmit FIFO has been sent out via USB.
4. The amount of data written to the transmit FIFO=Initial transmission size programmed by the application-Final transmission size after module update.
  - Amount of data sent via USB=(Initial packet count programmed by application-Final packet count after module update) ×MPSIZ[EPNUM]
  - Remaining data to be sent via USB=(Initial transmission size programmed by application-Data already sent via USB)

#### Internal Data Flow:

1. The application must set the transmission size and packet count fields in the specific endpoint's register, and enable the endpoint to transmit data.
2. The application must also write the required data to the transmit FIFO of this endpoint.
3. Each time the application writes a data packet to the transmit FIFO, the transmission size of this endpoint is automatically decremented by the size of the data packet. The application continuously fetches data from memory to write into the transmit FIFO until the transmission size of this endpoint becomes 0. After writing data to the FIFO, the "packet count in FIFO" counter increments (this is a 3-bit counter maintained internally by the module, with one counter per IN endpoint transmit FIFO. In the IN endpoint FIFO, the maximum number of data packets maintained by the module is always eight.) For zero length packets, each FIFO has an additional dedicated flag indicating no data is present in the FIFO.
4. When data is written to the transmit FIFO, the module will send out this data upon receiving an IN token. For each packet sent out and receiving an ACK handshake signal in response, the packet count of this endpoint will decrement by 1 until the packet count reaches 0. Upon timeout, the packet count does not decrement.
5. For zero length packets (indicated by the internal zero length flag), the module issues a zero length packet in response to the IN token and decrements the packet count field value.
6. If an IN token is received for an endpoint whose corresponding FIFO has no data and its packet count field is zero, the module will generate an "IN token received when TxFIFO is empty" (ITTXFE) interrupt for that endpoint (provided the NAK bit of the endpoint is not set to 1). The module returns a NAK handshake signal on this asynchronous endpoint.
7. The module internally resets the FIFO pointer to the beginning and does not generate a timeout interrupt.
8. When the transmission size is 0 and the packet count is 0, the transmission complete (XFRC) interrupt for this endpoint will be generated, and the endpoint enable will be cleared.

#### Application Programming Sequence:

1. Program the USBHS\_DIEPTSIZx register using the transmission size and corresponding packet count.
2. Program the USBHS\_DIEPCTLx register using endpoint features, and set the CNAK and EPENA (Endpoint enable) bits to 1.
3. When sending a non-zero length data packet, the application must poll the USBHS\_DTXFSTSx register (where x is the FIFO number associated with the endpoint) to determine whether there is sufficient space in the data FIFO. Before writing data, the application can also use the TXFE bit (in USBHS\_DIEPINTx).

#### Universal Periodic IN Data Transmission

This section describes typical periodic IN data transmission

**Application Requirements:**

1. The application requirements 1, 2, 3, and 4 for universal non-periodic IN data transmission also apply to periodic IN data transmission (with slight modification to requirement 2).
  - The application can only send a number of data packets with the maximum packet size or several packets with the maximum packet size, plus a short packet at the end of transmission.  
To send multiple packets of the maximum packet size followed by a short packet at the end of transmission, the following condition must be met:  
Transmission size [EPNUM] =  $x \times \text{MPSIZ}[\text{EPNUM}] + \text{sp}$   
(Where x is an integer greater than 0, and the range of sp is 0-MPSIZ[EPNUM]-1)  
If (sp > 0), packet count [EPNUM] = x + 1  
Otherwise, packet count [EPNUM] = x;  
MCNT[EPNUM] = packet count[EPNUM]
  - The application cannot send a zero length packet at the end of transmission. The application can independently send a zero length data packet.
  - To send a single zero length data packet:  
Transmission size[EPNUM] = 0  
Packet count [EPNUM] = 1  
MCNT[EPNUM] = packet count[EPNUM]
2. The application can only schedule one frame of data transmission at a time.
  - $(\text{MCNT}-1) \times \text{MPSIZ} \leq \text{XFERSIZ} \leq \text{MCNT} \times \text{MPSIZ}$
  - PKTCNT = MCNT (in USBHS\_DIEPTSIZE)
  - If  $\text{XFERSIZ} < \text{MCNT} \times \text{MPSIZ}$ , the last transmitted packet will be a short packet.
  - Note: MCNT is in USBHS\_DIEPTSIZE, MPSIZ is in USBHS\_DIEPTLx, PKTCNT is in USBHS\_DIEPTSIZE, XFERSIZ is in USBHS\_DIEPTSIZE.
3. Before receiving the IN token, the application must write the complete data to be sent in the frame into the transmit FIFO. Upon receiving an IN token, the module will perform the operation for an empty transmit FIFO even if only 1 double word of data remains to be written for the frame to be transmitted. When the transmit FIFO is empty:
  - The synchronous endpoint will respond with a zero length data packet.
  - The interrupt endpoint will respond with a NAK handshake signal.

**Internal Data Flow:**

1. The application must set the transmission size and packet count fields in the specific endpoint's register, and enable the endpoint to transmit data.
2. The application must also write the required data to the transmit FIFO associated with this endpoint.
3. Each time the application writes a data packet to the transmit FIFO, the transmission size of this endpoint is automatically decremented by the size of the data packet. The application continuously fetches data from memory to write into the transmit FIFO until the transmission size of this endpoint becomes 0.
4. When the periodic endpoint receives an IN token, the module will start transmitting data from the FIFO (if data exists in the FIFO). If there is no complete data packet in the FIFO for the frame to be transmitted, the module will generate an "IN token received when Tx FIFO is empty" interrupt for this endpoint.
  - The synchronous endpoint will respond with a zero length data packet.
  - The interrupt endpoint will respond with a NAK handshake signal.

5. The packet count for an endpoint is decremented by 1 when:
  - For synchronous endpoints, when transmitting a zero length or non-zero length data packet
  - For interrupt endpoints, decrement when sending the ACK handshake signal.
  - When both the transmission size and packet count are 0, a transmission completed interrupt will be generated for this endpoint, and the endpoint enable bit will be cleared.
6. Within the "Periodic Frame Interval" (controlled by the PFIVL bit in USBFS\_DCFG), the module generates an IISOIXFR interrupt in USBHS\_GINTSTS whenever it detects that data in any synchronous IN endpoint FIFO—which should be empty in the current frame—has not been fully transmitted.

#### Application Programming Sequence:

1. Program the USBHS\_DIEPCTLx register using endpoint features, and set the CNAK and EPENA bits to 1.
2. Write the data to be transmitted in the next frame into the transmit FIFO.
3. Hardware triggers the ITTXFE interrupt (in USBHS\_DIEPINTx) indicating the application has not written all required data to the transmit FIFO.
4. If the interrupt endpoint is already enabled before detecting the interrupt, the interrupt will be ignored. If the interrupt endpoint is not enabled, enable this endpoint so that data can be sent upon receiving the next IN token.
5. When the hardware triggers the XFRC interrupt (in USBHS\_DIEPINTx) and no ITTXFE interrupt is generated in USBHS\_DIEPINTx, it indicates the success of a synchronized IN transmission,. When reading the USBHS\_DIEPTSIZx register, if the transmission size=0 and packet count=0 are always obtained, it indicates all data has been transmitted via USB.
6. Setting the XFRC interrupt (in USBHS\_DIEPINTx) indicates the successful completion of an interrupt IN transmission, regardless of whether the ITTXFE interrupt (in USBHS\_DIEPINTx) is generated. When reading the USBHS\_DIEPTSIZx register, if the transmission size=0 and packet count=0 are always obtained, it indicates all data has been transmitted via USB.
7. In the USBHS\_GINTSTS register, if the incomplete synchronous IN transmission (IISOIXFR) interrupt is set without any of the aforementioned interrupts being generated, it indicates that the module did not receive at least one periodic IN token in the current frame.

#### Incomplete Synchronization IN Data Transmission

This section describes the operations that the application must perform for incomplete synchronous IN data transmission

##### Internal Data Flow:

1. The synchronization IN transmission is considered incomplete when any of the following conditions are met:
  - The module received a corrupted sync IN token on at least one sync IN endpoint. At this point, the application detects an incomplete synchronous IN transmission interrupt (IISOIXFR bit in USBHS\_GINTSTS).
  - The application writes data to the transmit FIFO too slowly, and receives an IN token before completing the full data write to the FIFO. At this point, the application detects the "IN token received when TxFIFO is empty" interrupt in USBHS\_DIEPINTx. The application can ignore this interrupt, as it will eventually generate an incomplete synchronous IN transmission interrupt (IISOIXFR bit in USBHS\_GINTSTS) at the end of the periodic frame. The module will respond to the received IN token by sending a zero length data packet via USB.
2. The application must stop writing data to the transmit FIFO as soon as possible.

3. The application must set the NAK bit and disable bit of the endpoint.
4. The module will disable this endpoint, clear the disable bit, and trigger the "Endpoint Disable" interrupt.

#### Application Programming Sequence:

1. The application can ignore the "IN token received when TxFIFO is empty" interrupt in USBHS\_DIE-PINTx for any isochronous IN endpoint, as this will ultimately generate an incomplete synchronous IN transmission interrupt (in USBHS\_GINTSTS).
2. Hardware-triggered incomplete synchronous IN transmission interrupt (in USBHS\_GINTSTS) indicates there is at least one incomplete synchronous IN transmission, on a synchronous IN endpoint.
3. The application must read the "Endpoint Control" register of all synchronized IN endpoints to detect endpoints with incomplete IN data transmission
4. The application must stop writing data to the "Periodic Transmit FIFO" associated with these endpoints.
5. Program the following fields in the USBHS\_DIEPCTLx register to disable the endpoint:
  - SNAK=1 in USBHS\_DIEPCTLx
  - EPDIS=1 in USBHS\_DIEPCTLx
6. Hardware triggers the "Endpoint Disable" interrupt in USBHS\_DIEPINTx, indicating the module has disabled this endpoint.
  - At this point, the application must either empty the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling a new transmission endpoint in the next frame. To refresh the data, the application must use the USBHS\_GRSTCTL register.

#### Stop the Asynchronous IN Endpoint

This section describes how an application can stop an asynchronous endpoint.

#### Application Programming Sequence:

1. Disable the IN endpoint to be stopped. Set the STALL bit to 1 simultaneously.
2. EPDIS=1 in USBHS\_DIEPCTLx (when the endpoint is already enabled)
  - STALL=1 in USBHS\_DIEPCTLx.
  - The priority of the STALL bit is always higher than that of the NAK bit.
3. A hardware-triggered "Endpoint Disable" interrupt (in USBHS\_DIEPINTx) notifies the application that the module has disabled the specified endpoint.
4. The application must empty the non-periodic or periodic transmit FIFO based on the endpoint type. For non-periodic endpoints, the application must re-enable another non-periodic endpoint without stopping to transmit data.
5. When the application is ready to end the STALL handshake signal for this endpoint, it must clear the STALL bit in USBHS\_DIEPCTLx.
6. If the application sets or clears the STALL state of an endpoint upon receiving a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command from the host, the STALL bit must be set to 1 or cleared before the status phase transfer of the control endpoint.

#### Special Case: Stop Controlling the OUT Endpoint

During the data phase of a control transmission, if the number of IN/OUT tokens sent by the host exceeds the value specified in the SETUP packet, the module must respond with STALL to these excess IN/OUT tokens. In this scenario, the application must enable the ITTXFE interrupt of USBHS\_DIEPINTx and the OTEPDIS interrupt of USBHS\_DOEPINTx during the data phase of the control transmission (when the module has completed transmitting the data amount specified by the SETUP packet). Subsequently,

when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register to 1 and clear this interrupt.

## 34.6 Register Description

The application controls the USBHS module by performing read and write operations on the control and status registers through the AHB slave interface. All registers in the USBHS module are 32-bit registers with 32-bit aligned addresses, and can only be accessed in 32-bit mode.

Control and status registers are categorized as follows:

- USBHS System Control Register
- Module Global Register
- Host Mode Register
- Device Mode Register
- Power and Clock Gating Control Registers
- Data FIFO(DFIFO) Access Register

The USBHS system control register has a different base address from other registers. This register is independent of the USBHS module and controls the relevant settings of the USBHS module.

Only the module global register, power and clock gating control registers, and data FIFO access registers can be accessed in both host and device modes. When the USBHS module operates in one mode (host or device), the application must not access registers in the alternate role mode, such as accessing device mode registers while in host mode. If an illegal access occurs, a mode mismatch interrupt will be generated and reflected in the module interrupt register USBHS.GINTSTS.NMIS bit. When the module switches from one role mode to another, the registers in the new operating mode must be reprogrammed to the power on reset state.

### Control Status Register Memory Mapping

The host and device mode registers occupy different addresses. All registers are implemented within the AHB clock domain.

Figure 34-7 USBHS Control and Status Register Memory Mapping

### 34.6.1 Register List

USB system control register base address: 0x40055400

Table 34-3 USB System Control Register Offset

| Offset | Register     | Description                 | Width |
|--------|--------------|-----------------------------|-------|
| 0x00   | USB_SYCTLREG | USB System Control Register | 32    |

USBHS module register base address: 0x400C0000

Table 34-4 USB 2.0 High-Speed Module USBHS Register Offset

| Offset      | Register        | Description                                             | Width |
|-------------|-----------------|---------------------------------------------------------|-------|
| 0x00        | USBHS_GVBUSCFG  | VBUS Control Register                                   | 32    |
| 0x08        | USBHS_GAHBCFG   | AHB Control Register                                    | 32    |

### 34.6.3 USBHS Global Register

These registers are available in both host and device modes and do not need to be reprogrammed when switching between the two modes.

#### 34.6.3.1 VBUS Control Register (USBHS\_GVBUSCFG)

This register can be used to set the VBUS value to ignore the state of the VBUS pin.

### 34.6.3.2 AHB Control Register (USBHS\_GAHBCFG)

This register can be used to configure the module after power-on or when changing role modes, mainly containing AHB system-related configuration parameters.

The application must program this register before starting any AHB or USB transactions. Do not change this register after initial programming.

### 34.6.3.3 USB Configuration Register (USBHS\_GUSBCFG)

This register can be used to configure the module after power on or when changing role modes. It contains configuration parameters related to USB and USB-PHY.

The application must program this register before starting any AHB or USB transactions. Do not change this register after initial programming.

| 2:0 | TOCAL | FS timeout calibration | <p>The additional latency introduced by the PHY includes the number of PHY clocks set by the application in this field, as well as the module's full-speed inter-packet timeout interval. The impact of delays introduced by different PHYs on the data line state varies. The standard USB timeout value for full-speed operation ranges from 16 to 18 bit times (inclusive). The application must program this field according to the enumeration speed. The number of bit times added per PHY clock is 0.25 bit times.</p> <div>  <b>Note</b><br/>           Active in both device and host modes.         </div> | RW     |

## 34.6.3.4 Reset Register (USBHS\_GRSTCTL)

The application resets various hardware features in the module through this register.

|     |       |                 | <p>and used to control the interrupt status must be cleared.</p> <p>Since the interrupt status bit is not cleared, the application can obtain the status of all module events that occurred after this bit was set to 1. This bit is self-clearing; the module will clear this bit after all necessary logic is reset. This process requires several clock periods, depending on the current state of the module.</p> <div>  <b>Note</b><br/>           Active in both device and host modes.         </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |
| 0   | CSRST | Core soft reset | <p>Reset the HCLK and PCLK domains as follows:<br/>Clear individual interrupt and all CSR register bits except:</p> <ul style="list-style-type: none"> <li>● GATEHCLK bit in USBHS_GCCTL</li> <li>● STPPCLK bit in USBHS_GCCTL</li> <li>● FSLSPCS bit in USBHS_HCFG</li> <li>● DSPD bit in USBHS_DCFG</li> </ul> <p>Reset all module state machines (excluding AHB slaves) to idle state and flush all transmit FIFOs and receive FIFOs.</p> <p>At the end of the last data phase in an AHB transmission, terminate all transactions on the AHB master as soon as possible. Terminate all USB transactions immediately.</p> <p>The application can perform a write operation to this bit at any time when a reset of the module is required. This bit is self-clearing. The block will clear this bit after all necessary logic is reset, which requires several clock periods depending on the current state of the module. Once this bit is cleared, software must wait for at least 3 PHY clock periods before accessing the PHY domain (synchronization delay). Additionally, the software must wait until bit 31 in this register is set to 1 (indicating the AHB master is idle) before it can start operation.</p> <p>Software reset is typically used in two scenarios: first, during software development, and second, after the user dynamically modifies the PHY selection bit in the aforementioned USB configuration register. When the user modifies the PHY, the corresponding clock will be selected for the PHY and used in the PHY domain. Once a new clock is selected, the PHY domain must be reset to ensure normal operation.</p> <div>  <b>Note</b><br/>           Active in both device and host modes.         </div> | RW     |

### 34.6.3.5 Global Interrupt Status Register (USBHS\_GINTSTS)

This register is used to interrupt the application via system-level events in the current mode (Device Mode or Host Mode). This register indicates the current mode.

The FIFO status interrupt is read-only; if software performs read and write operations on the FIFO while processing these interrupts, the FIFO interrupt flag will be automatically cleared.

Before enabling the interrupt bit, the application must clear the USBHS\_GINTSTS register during initialization to avoid any interrupts before initialization.

| 22  | DATAFSUSP | Data fetch suspended | <p>This interrupt is only active in DMA mode. This interrupt indicates that the module has stopped fetching data for the IN endpoint due to unavailable TxFIFO space or request queue space. The application uses this interrupt in the endpoint mismatch algorithm. For example, after detecting an endpoint mismatch, the application will perform the following operations:</p> <ul style="list-style-type: none"> <li>● Set the global non-periodic IN NAK handshake signal to 1</li> <li>● Disable IN endpoint</li> <li>● Clear FIFO</li> <li>● Determine the token sequence based on the IN token sequence learning queue</li> <li>● Re-enable endpoint</li> <li>● Clear global non-periodic IN NAK handshake signal</li> </ul> <p>If the global non-periodic IN NAK has been cleared but the module has not yet retrieved data from the IN endpoint, and an IN token is received simultaneously, the module will generate an "IN token received while FIFO is empty" interrupt. Then USBHS sends a NAK response to the host. To avoid the above situation, the application can check the DATAFSUSP interrupt in USBHS_GINTSTS, which ensures the global NAK handshake signal is cleared only after the FIFO is full. Additionally, the application can mask the "Interrupt upon receiving IN token when FIFO is empty" while clearing the global IN NAK handshake signal.</p> <p>Writing 1 to this bit clears it via software.</p> <div>  <b>Note</b><br/>           Active only in device mode.         </div> | RW     |

| 7   | GONAKEFF        | Global OUT NAK effective interrupt             | <p>Indicates that the "Set global OUT NAK to 1" bit (SGONAK bit in USBHS_DCTL register) set by the application has taken effect in the module. By writing to the "Clear Global OUT NAK" bit (CGONAK bit in USBHS_DCTL register), this bit can be cleared.</p> <div>  <b>Note</b><br/>           Active only in device mode.         </div>                                                                                                                                                                                                                                                                                                                                  | RO     |
| 6   | GINAKEFF        | Global IN non-periodic NAK effective interrupt | <p>Indicates that the "Set global non-periodic IN NAK to 1" bit (SGINAK bit in USBHS_DCTL) set by the application in the USBHS_DCTL register has taken effect in the module. That is, the module has sampled the global IN NAK bit set by the application, and the result has taken effect. This bit is cleared by clearing the Clear Global Non-periodic IN NAK bit in the USBHS_DCTL register (CGINAK bit in UBSFS_DCTL). This interrupt does not necessarily indicate that a NAK handshake has been sent on the USB. The priority of the STALL bit is higher than that of the NAK bit.</p> <div>  <b>Note</b><br/>           Active only in device mode.         </div> | RO     |

### 34.6.3.6 Global Interrupt Mask Register (USBHS\_GINTMSK)

This register is used in conjunction with the global interrupt status register (USBHS\_GINTSTS) to interrupt the application. If an interrupt bit is masked, the corresponding interrupt will not be generated, but the associated register bit will still be set to 1.

| Offset | Bit Position |         |        |          |         |        |      |        |          |            |                      |           |       |       |          |       |          |          |         |          |        |          |           |           |         |        |      |          |       |          |   |   |

### 34.6.3.7 Receive Status Debug Read/Status Read and Pop Register (USBHS\_GRXSTSR/USBHS\_GRXSTSP)

Reading the receive status debug read register returns the content at the top of the receive FIFO.

Reading the receive status read and pop register can additionally pop the data entry at the top of the RxFIFO. The interpretation of the receive status content differs between host mode and device mode.

When the receive FIFO is empty, the module ignores read or pop operations on this register and return the value 0x0000 0000. When the receive FIFO non-empty bit (RXFNE bit in USBHS\_GINTSTS) of the module interrupt register is set, the application must only pop the receive status FIFO.

The read offset address (Offset) : 0x1C

The pop offset address (Offset) : 0x20

#### Host Mode

| Offset | Bit Position |    |    |    |    |    |    |    |    |    |    |    |        |    |      |    |      |    |    |    |    |    |   |   |   |   |       |   |   |   |   |   |  |  |
